# CONTENTS AND INDEX.

NEW SERIES. VOL. XXXVII.—JANUARY TO JUNE, 1913.

*The Names of Contributors are given in Capitals.*

- A., J. A., Michigan Bird Life, W. B. BARROWS, 372; Mammals, G. S. MILLER, JR., 453  
 ABDERHALDEN, E., Ferments, J. AUER, 837  
 ACADEMIC, Costume, B. G. WILDER, 178; J., 371; T., 488; Freedom, J. E. CREIGHTON, 450, 602; H. LEFFMAN, 602  
 ACCOUNTS OF LEARNED SOCIETIES, A. B. HART, 66; S. N. PATTEN, 371  
 ADAMS, G. I., Segment and Segmentation, 177  
 AEROPHANE, Gyroscopic Forces in, E. V. HUNTINGTON, 484  
 AGE AND FECUNDITY, R. PEARL, 226  
 AGRICULTURAL, College, Educational Standards at, B. H. HIBBARD, 751; Research, Endowed, R. PEARL, 707; E. DAVENPORT, 907  
 ALDER, J., and A. HANCOCK, British Tunicata, W. E. RITTER, 451  
 ALDRICH, J. M., University Life in Idaho, 943  
 ALLEE, W. C., Molting in Isopods, 882  
 ALLEGHANY VALLEY EROSION, E. H. WILLIAMS, JR., 447  
 ALPINE LABORATORY, F. E. CLEMENTS, 327  
 AMERICAN ASSOC. FOR THE ADVANCEMENT OF SCIENCE, Address of President, 1; Proceedings Cleveland Meeting, 41; Section A, 76; Section B, 119; Section H, 133; Section I, 159; Section F, 199; Section H, 275, 341; Section K, 389; Section E, 501; Section D, 568; Pacific Coast Meeting, 660; Council, 661; Chem. Soc., 299; C. L. PARSONS, 674; Geog. Soc., A. P. BRIGHAM, 210; Math. Soc., F. N. COLE, 115, 460, 845; Museum Nat. Hist., Pensions, 827; Philos. Soc., 232, 425, 690; and President Wilson, 476; A. W. GOODSPEED, 718; Physiol. Soc., J. ERLANGER, 232; Soc. Agric. Engineers, I. W. DICKERSON, 235; Soc. for Pharmacol. and Exp. Therapeutics, J. AUER, 193; Soc. of Zool., W. C. CURTIS, 261  
 AMPHIBIA, Ancestry of, W. K. GREGORY, 806  
 ANESTHETICS, W. J. V. OSTERHOUT, 111; R. S. LILLIE, 765, 959  
 ANTHROPOLOGICAL Soc. of Wash., W. H. BABCOCK, 77, 158, 236, 349, 387, 499, 538, 578, 614, 884  
 ANTHROPOLOGY at CLEVELAND, G. G. MACCURDY, 341  
 APPALACHIANS, B. K. EMERSON, 20  
 ARCHIBALD, R. C., Eloge Académique, G. Darboux, 983  
 ARTHUR, J. C., New Weed Exterminator, 19  
 ASTRONOMICAL AND ASTROPHYS. Soc. of Amer., P. FOX, 25, 639  
 ATKINSON, G. F., Enothera, 716  
 AUER, J., Ferments, E. ABDERHALDEN, 837  
 AVOGADRO'S LAW, J. LOEB, 427  
 BABCOCK, W. H., Anthropol. Soc. of Wash., 77, 158, 236, 349, 387, 499, 538, 578, 614, 884; Grana de Brasile, 304  
 BACTERIA AND FREEZING POINT OF WATER, S. C. KEITH, JR., 877  
 BAKER, F. C., Interglacial Records in N. Y., 523  
 BALLS, W. L., Cotton Plant, T. H. K., 634  
 BANKS, N., Notes on Entomology, 530; Entomology, C. Schröder, 872  
 BARDEEN, C. R., Anatomy of Vertebrates, J. S. KINGSLEY, 148  
 BARKER, L. F., Diagnosis and Therapy, 731  
 BARNETT, S. J., Relativity, 113, 560; Electricity and Magnetism, S. G. STARLING, 415  
 BARROWS, W. B., Michigan Bird Life, J. A. A., 372  
 BARROWS, W. E., Light, Photometry and Illumination, E. C. CRITTENDEN, 109  
 BASIN-RANGE STRUCTURE, C. R. KEYES, 226; S. PAIGE, 710  
 BASKERVILLE, C., Rarer Elements, P. E. BROWNING, 109  
 BELL, J. M., Elisha Mitchell Sci. Soc., 158, 388  
 BENEDICT, R. C., Food, 792  
 BERKEY, C. P., New York Acad. Sci., 958  
 BERRY, E. W., Geology of Paris, P. LEMOINE, 257; Pithecanthropus erectus, 418; Paleobotanical Yearbook, Jongman, 670  
 BESSEY, C. E., Botanical Science, 1; Botanical Notes, 337, 417, 492, 915; Trees in Winter, A. F. BLAKESLEE and C. D. JARVIS, 528  
 BEUTNER, R., Mathematics for Scientists and Physicians, J. Salpeter, 947; and J. LOEB, Bioelectrical Potential Differences, 672  
 BIGELOW, M. A. and A. N., Biology, J. G. NEEDHAM, 714  
 BILLINGS, JOHN SHAW, 512  
 BIOELECTRICAL POTENTIAL DIFFERENCES, J. LOEB and R. BEUTNER, 672  
 BIOLOGICAL Soc. of Wash., D. E. LANTZ, 425, 808  
 BISSELL, G. W., Section D—Amer. Assoc., 568  
 BJERKNES and SANDSTRÖM'S Meteorology, F. R. SHARPE, 223  
 BLAKESLEE, A. F., Labeling Surface for Glassware, 561; Sex in Mucors, 880  
 BLAKESLEE, A. F., and C. D. JARVIS, Trees in Winter, C. E. BESSEY, 528  
 BLANCKENHORN, M., Nat. Hist. of Dead Sea, E. HUNTINGTON, 635  
 BLOCKS AND SEGMENTS, A. J. UDDEN, 709  
 BLODGETT, F. H., Conn's Biology, 218  
 BOLL-WEevil, O. F. COOK, 259  
 BOTANICAL, Notes, C. E. BESSEY, 337, 417, 492, 915; Science, C. E. BESSEY, 1; Soc. of Amer., G. T. MOORE, 373; Soc. of Wash., C. L. SHEAR, 157, 312, 461, 883, 921; Taxonomy, W. T. SWINGLE, 864  
 BOTANY, Old and New, W. G. FARLOW, 79; E. B. COPELAND, 756  
 BOVIE, W. T., Proteins, 24, 373  
 BOWMAN, I., Assoc. of Amer. Geographers, 235  
 BOWMAN EXPEDITION, 702  
 BRAGG, W. H., Radioactivity, R. A. MILLIKAN, 492  
 BRANNER, J. C., Flowing Road, C. Whitney, 151  
 BRIDGES, C. B., Sex-linkage, 112

- BRIGHTMAN, A. P., *Amer. Geog. Soc.*, 210; *Geographical Discovery*, E. HEAWOOD, 668

NEW SERIES  
VOL. XXXVII. No. 940

FRIDAY, JANUARY 3, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

## Saunders' New Books

### Brill's Psychanalysis

APPLICATION OF  
FREUD'S THEORIES

This one volume gives you the practical application of all Freud's theories, and it gives it to you from the pen of a man thoroughly competent to write on this subject. Psychanalysis is the only system of psychotherapy that deals with the neuroses as entities instead of treating symptoms, as do hypnotism, suggestion, and persuasion. The results of psychanalysis are most effective. It is only through psychanalysis you can gain a real insight into the neuroses and psychoses. You will find Brill's work most valuable.

Octavo of 337 pages. By A. A. BRILL, Ph.B., M.D., Clinical Assistant in Psychiatry and Neurology at Columbia University Medical School. Cloth, \$3.00 net.

### Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. Not only does this work give the salient facts of structural zoology and the development of the various branches of animals, but also the natural history—the *life and habits*—thus showing the interrelations of structure, habit and environment.

Part I—*Field and Laboratory Guide*: 12mo of 275 pages, interleaved. Cloth, \$1.25 net. Part II—*Principles*: 12mo of 406 pages, illustrated. Cloth, \$2.00 net. By L. S. DAUGHERTY, M.S., Ph.D., Professor of Zoology, State Normal School, Kirksville, Mo.; and M. C. DAUGHERTY, author with Jackson of "Agriculture Through the Laboratory and School Garden."

### Stiles' Nutritional Physiology

This new work expresses the most advanced views on this important subject. It discusses in a concise way the processes of digestion and metabolism. The key word of the book throughout is "energy"—its source and its conservation.

12mo of 295 pages, illustrated. By PERCY GOLDTHWAIT STILES, Assistant Professor of Physiology at Simmons College, Boston. Cloth, \$1.25 net.

W. B. SAUNDERS COMPANY

West Washington Square, Philadelphia

Smithsonian Institution

JAN 4 1913

# NEW MCGRAW-HILL BOOKS

## IMPORTANT DECEMBER ISSUES

### PALMER—The Theory of Measurements

By A. deFOREST PALMER, Ph.D., Associate Professor of Physics in Brown University. 248 pp. with Tables and Diagrams. \$2.50 (10/6) net, postpaid.

A thorough discussion of the principles underlying the precision of measurements, and the development of suitable methods of measurement for special purposes.

### NORTHRUP—Methods of Measuring Electrical Resistance

By EDWIN F. NORTHRUP, Ph.D. 389 pp. Illus. \$4.00 (17s) net, postpaid.

An authoritative treatise of value not only to physicists and teachers but to men in practice as well. It describes and gives methods, sample measurements, details of instruments, etc.

### HAVARD—Refractories and Furnaces

By F. T. HAVARD, E.M., Consulting Metallurgist, Goldsmith Bros.; Associate Professor of Metallurgy, University of Wisconsin. 356 pp. fully illus. \$4.00 (17s) net, postpaid.

Based on a long experience in charge of furnaces in Germany, England and the United States. Covers fully the preparation, properties, etc., of furnace materials.

## JANUARY PUBLICATIONS

### HOBERT—Design of Polyphase Generators and Motors

By HENRY M. HOBERT, M. Inst. C.E., Consulting Eng., G. E. Co. 265 pp. Illus. \$3.00 (12/6) net, postpaid. Covers fundamental outlines, clearly and thoroughly.

### GRAY—Electrical Machine Design

By ALEXANDER GRAY, Professor of Electrical Engineering, McGill University. 524 pp. 649. 300 illus. \$4.00 (17s) net, postpaid.

A textbook on both A.C. and D.C. machine design based on a practical plus a teaching experience.

### International Chemical Series

HENRY P. TALBOT, Ph.D., Consulting Editor.

The books below which are the first in this series have had a gratifying reception. They are distinctive volumes of high standard both in text and manufacture.

### NORRIS—The Principles of Organic Chemistry

By JAMES F. NORRIS, Ph.D., Professor of Chemistry, Simmons College, Boston. 570 pp. 5½x8. Illustrated. \$2.50 (10/6) net, postpaid.

### CADY—Inorganic Chemistry

By HAMILTON PERKINS CADY, A.B., Ph.D., Professor of Chemistry, University of Kansas. 629 pp., 5½x8. Illustrated. \$2.50 (10/6) net, postpaid.

## RECENT MINERALOGICAL AND GEOLOGICAL BOOKS

### ROGERS—Study of Minerals

A Combined Text Book and Pocket Manual

By Austin Flint Rogers, Ph.D., Assoc. Prof. Leland Stanford Univ. 522 pages, 5x7½. Flexible leather. \$3.50 (15s) net, postpaid.

Prof. Rogers' work has received the endorsement of nearly all of the important schools of the country.

### GUNTHER—The Examination of Prospects

By C. Godfrey Gunther, E.M. 222 pages, 79 illus. Leather, \$2.00 (8/4) net, postpaid.

### FARRELL & MOSES—Practical Field Geology.

By J. H. Farrell, E.M., Mining Geologist.

A Guide to the Sight Recognition of 120 Common or Important Minerals

By Alfred J. Moses, E.M., Ph.D., Prof. Columbia University. 271 pages, illustrated. Leather. \$2.50 (10/6) net, postpaid.

### WEINSCHENK—Petrographic Methods

By E. Weinschenk. Trans. by Robt. W. Clark, Instructor in Petrography, Univ. of Mich. 396 pp. 371 illus., \$3 50 (15s) net, postpaid.

SOME OF THE NEXT STEPS IN BOTANICAL SCIENCE<sup>1</sup>

## CONTENTS

<i>The American Association for the Advancement of Science:—</i>	
<i>Some of the Next Steps in Botanical Science:</i> PROFESSOR CHARLES E. BESSEY . . . .	1
<i>Recent Explorations in Siberia:</i> DR. A. HEDLIČKA . . . . .	13
<i>The Reorganization of the Medical Department of the University of California . . . . .</i>	14
<i>Scientific Notes and News . . . . .</i>	14
<i>University and Educational News . . . . .</i>	18
<i>Discussion and Correspondence:—</i>	
<i>A New Weed Exterminator:</i> PROFESSOR J. C. ARTHUR. <i>Greek Refinements in Architecture:</i> DR. EDWARD S. HOLDEN. <i>The Question of the Older and Newer Appalachians:</i> PROFESSOR B. K. EMERSON . . . .	19
<i>Scientific Books:—</i>	
<i>Dakin on Oxidations and Reductions in the Animal Body:</i> PROFESSOR LAFAYETTE B. MENDEL. <i>Walker on North American Dragon Flies:</i> PROFESSOR T. D. A. COCKERELL . . . .	21
<i>Special Articles:—</i>	
<i>A Preliminary Note on the Coagulation of Proteins by Ultraviolet Light:</i> W. T. BOVIE . . . .	24
<i>The Astronomical and Astrophysical Society of America:</i> PHILIP FOX . . . . .	25
<i>Societies and Academies:—</i>	
<i>The New Orleans Academy of Science:</i> PROFESSOR R. S. COCKS . . . . .	40

WHEN one who has worked long in any field of science speaks before an audience such as this he is expected to say something about the condition of his branch of science when he began work with meager and poorly adapted apparatus, to contrast it with its greatly improved condition to-day, and to dwell with pride upon the finely equipped laboratories with costly apparatus especially designed for particular experiments, to be found by the twentieth century scientific student. And I must confess that the temptation to do so was one difficult to resist, for we who have grown old in years are fain to dwell upon the days of long ago with the garrulity which comes with gray heads and withering muscles. It has seemed to me wiser, however, that this evening we should look into the future rather than into the past, for in that direction lies the possibility of progress, and it is of progress that I wish to speak.

## THE BOTANY OF YESTERDAY

Yet in order that we may properly orient ourselves with reference to the area covered by the science of botany to-day, we shall have to go back a few decades to understand what additions have been made to its territory during this period of expansion. For the shrewd observer can not avoid the conclusion that botany has shared with the world powers in a territorial growth which has extended its boundaries far beyond those known to the fathers, and

<sup>1</sup> Address of the president of the American Association for the Advancement of Science, Cleveland, December, 1912.

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

we have annexed much contiguous and even some remote territory in a most imperialistic fashion. It may be comforting to some people to know that during all this time there have been those who have constantly and consistently lifted up their voices in protest against this contravention of the practise of the fathers, and the breaking down and removal of the ancient landmarks. In all these years there have been botanical anti-expansionists, but like their brothers in the national field they have been overwhelmed, and the tide of expansion has swept on unchecked.

Consider for a few minutes the botany of forty years ago, when you could count on the fingers of one hand the American colleges that had chairs of botany. And here I use the term chair advisedly, for they were literally chairs and not departments, much less laboratories. And everywhere else in the colleges of the country the chairs of botany were represented by what Holmes so aptly called "settees" from the number of subjects taught therefrom. The botany dispensed from these chairs was the delightful study of the external morphology of the higher plants, especial emphasis being laid upon the structure of flowers and fruits. And it may truly be said here that often the teaching was done very well, far better than many a botanist to-day is wont to imagine. I am pretty sure that in general the teaching was as successfully done then as it is now. There were some poor teachers then as there are now, and there were some inspiring teachers then who touched their pupils with the sacred fire, as there are now some who have had a divine call to teach and inspire and help.

And with this external morphology there was always associated the classification of the higher plants, in its simpler form the pleasurable pastime of identifying the plants of the neighborhood, and in its more advanced form represented by the

work of Torrey and Gray and Vasey and Engelmann. And we should judge the systematic botany of that day by the work of these masters and not by the diversions of its amateurs; and you will agree with me that so judged the systematic botany of that period will not fall short of any standard we have set up in these later days.

The botany of that day was not without its laborious investigations and its tangible results. Every new area was a great out-of-doors laboratory to be diligently studied from border to border. That was the day of the founding of many small botanical gardens, and small local herbaria, some of which having served their purpose disappeared long since, while others have grown into the great and flourishing institutions of to-day.

This much as to the botany of the immediate past; the phase of the science in which the older living botanists were trained.

#### PRESENT-DAY BOTANY

And what of the botany of to-day? Let us consider for a little the present condition of the science.

*It is Unorganized.*—The personnel of botany has greatly increased with the great increase in the territory it now includes. This personnel, it must be said, is still quite heterogeneous. Some of us are largely self-taught, so far as the major part of the subject is concerned. We brought to our work the results of the meager teaching of the old-time college class-rooms, and year by year we have enlarged the borders of our own departments as we have added to our own knowledge of the subject by means of our laboratories and libraries. Thus we have built all kinds of superstructures upon the foundations supplied by our teachers. As a consequence the science is yet largely unorganized and lacks consistency in plan and

purpose. Here and there a dominant man has wrought out a scheme of the science for himself, but how familiar is the fact to all of us that there is yet no agreement even upon so small a question as to the content of the first year of college botany, or the mode of its presentation. There is moreover a vagueness as to the boundaries of the science, some botanical teachers wandering far across the border into the domain of some contiguous science, or still more commonly into the more or less practical applications of some portions of botany. This latter indiscretion is especially noticeable in the textbooks prepared for the secondary schools, in some instances by botanists of good standing. If this were done by the agriculturists, the agronomists, the horticulturists, the foresters and others in similar lines of work with plants, it would not be surprising, but when this is done by botanists it is significant of the unorganized condition of the science. With a fuller knowledge of the science there must come a clearer vision of what it is, and what it is not, and we shall no longer find textbooks of botany made to include so much that is not botany, while leaving out so much that is botany.

This difference of opinion as to what constitutes botany results in the absence of united effort. In its simplest aspect it takes the familiar form of uncertainty as to the content and value of the work done by the student elsewhere when he transfers himself from one college to another. As a matter of fact there is yet no agreement as to what is a standard first-year's course in college botany. What teacher has not been sorely puzzled to know to what courses to admit men who came from another college with credits in botany! It is quite unscientific to try to account for this condition by an excusatory reference to the individual peculiarities and the per-

sonal differences of the teachers. In science we consider the personal equation as something to be determined and eliminated, and not to be excused and tolerated. Every difference in the treatment of, say the first-year course, is just so far an indication of a more or less unscientific attitude by one or all of the teachers concerned. We work in this haphazard, disconnected way either because we do not know any better, or knowing better we think it not worth while. Either horn of this dilemma is equally unworthy of our acceptance. Ignorance is no valid excuse for the scientific man, and in science everything is worth while. It is to our shame as botanists that we acknowledge our inability hitherto to frame a standard first-year course in college botany. When the science is definitely formulated in the minds of botanists the present disagreement will no longer exist. Surely we now "see as through a glass darkly."

*The Applications of Botany.*—Again, it may be remarked that we are to-day placing great emphasis upon the applications of botany to some of the great human activities, especially to agriculture. Witness the agricultural experiment stations with their botanists of all kinds, from those who study weeds and poisonous plants, to the physiologists, pathologists, ecologists and plant breeders. And as we look over the work they do we are filled with admiration and pride that they have individually done so well. But it is not the cumulative work of an army of science, it is rather the disconnected, unrelated work of so many individuals. They are doing scientific work in an unscientific way. There is as yet no movement of a united army of science; it has been rather a sort of guerrilla warfare against the common enemy. We lack organization, and like unorganized soldiers we make little headway in spite of

individual learning and efficiency. Botanical science which should have guided and directed these laudable applications has not kept pace with them, and we have the spectacle of these economic botanists, physiologists, pathologists, plant breeders and others working apart from the botanists proper, and sometimes even disclaiming any allegiance to the parent science. Nothing but confusion and disaster can result from such a condition.

*Lack of Cooperation.*—Contrary to what is sometimes affirmed, botanists are still studying the flora of the country. In some quarters there has been expressed the fear that field botany has disappeared from the schools and colleges; but this is far from true. While it no longer claims the larger part of the student's attention, it is still an essential part of the training of every botanist, and it is probably true that in some cases there is even more field work required to-day of young botanists than its importance demands. Certainly in one kind of field work I should like to see some of the energy and ability now given to the discovery of means for splitting old species turned towards the solution of problems pertaining to growth, and development, and reproduction. But the careful field study of what plants grow here and there, and why they do so, is greatly to be commended. The sociology of plants, or as we call it, ecology, has given in the last few years a new reason, as well as a new direction to field botany.

The systematic botany of to-day continues to concern itself more with the distinction of species than with their origin, and this has brought to this department of the science an increased narrowness which has greatly injured its usefulness. On the other hand plant breeding, which should be the experimental phase of systematic botany, has had no connection with

it. And strangely, systematic botany, which should welcome plant breeding as an ally in its quest as to the meaning and origin of species, has been scarcely at all interested. It has been left to the florists, the horticulturists and the agronomists to patronize the new phase of botany, and this they have done, in spite of the new and quite unnecessarily formidable terminology so rapidly developed by the breeders. So what might have proved to be one of the most helpful aids to the solution of the greatest of biological problems—how living things have come to be what they are—is allowed to fret out its life by beating vainly against the technical bars of its Mendelian cage. I know of no better illustration of the unorganized condition of botanical science than this failure of the systematic botanists and the plant breeders to work together for a common end.

#### THE BOTANY OF TO-MORROW

But I have dwelt enough upon the past and the present, and I feel inclined to apologize to you for having turned your faces so long backward. For while we must consider what has been, we can make progress only by planning for what is to be. So let us turn now to the future of botanical science, and endeavor to trace its more profitable course of development during the next one or two decades. What are seemingly to be the demands of modern society upon this science? What are to be some of the next steps in its evolution? For whatever we may say in regard to the independence of science we can not escape the fact that it must serve its "day and generation." No science can hope for support or recognition that does not respond to the demands of its age. And yet we must not ignore the labors of those pioneers in every science who foresee possibilities that are hidden from the mass of men.

There must always be place provided for the few seers who see to-day what is now hidden from mankind in general, and may continue to be so hidden for generations, or centuries. All honor to these prophets who prepare the way for the oncoming of scientific truth, but it is true, nevertheless, that it is only when such truth has permeated contemporary society that science thrives.

*Its Content.*—Looking forward, then, let us try to see the trend of that branch of science which deals with plants, the science which I have the honor of representing on this platform this evening. And my first inquiry may well concern itself with the content of botanical science in the immediate future. As we become better acquainted with it and recognize more clearly its relations to the activities of the community we shall be able to define its proper content with more accuracy. And let no man attempt to belittle the importance of such an undertaking. It is not useless to attempt to fix the boundaries of any field of human endeavor, especially in such a one as this which deals with so vast a number of individual objects, each having many possible relations to one another and to ourselves. I am well aware of the impossibility of absolutely delimiting botany from every other science, and especially of doing so with reference to many of its applications, and I am fully aware of the fact that the limits of any science are subject to change with the progress of human knowledge. Now and then there must be a "rectification of the frontier" in respect to the boundaries of a science, as with the boundaries of a great empire, as its farther provinces and the exact location of rivers and mountain ranges become better known. So without doubt we shall have to add to or subtract from the area now allotted to botany; and yet I feel that it is worth our

while to spend a little time in indicating its present boundaries and content.

With all the details that may be insisted upon by some specialists it still is true that the field of botany may be considered in three parts, structure, physiology and taxonomy. Beginning with such structures as are obvious to our unaided eyes we have carried our studies to the minute structure of the tissues, and the cells which compose them. We are able now to peer into the protoplasmic recesses of the living cell, and while we can not say that we have seen life, we have seen where life is, and what it does. Cytology, histology and morphology in our modern laboratories have greatly changed our conception of the structure of the plant. It is no longer made up of forms to be compared because of their general similarity of outline, or of position in the plant body. The plant as a whole is a community of variously differentiated living units, just as is each of its organs. It is a complex community in which there is a measure of individual independence of the units, along with much of mutual dependence.

This leads me easily to that portion of the field of botany that has to do with the activities of plants and their organs—physiology—whose scope has been so greatly extended in these later years. Here such inquiries as those pertaining to nutrition, growth, sensibility, reproduction are of primary importance. The introduction of the experimental method of inquiry has made this a favorite department of the science. Who does not enjoy catching a plant, tying it up in a corner and compelling it to do something, while we watch for the result? This kind of study appeals especially to those who are looking for demonstrations, and for this reason plant physiology has been increasingly popular. Some botanists indeed have gone so far as to insist upon

giving first place to physiology, probably because of its ready appeal to our senses. It is easy to interest a boy in the thing that responds, whether it be a kicking frog stimulated by an electrical discharge, or a green plant whose stimulation is a properly directed beam of sunlight. And yet it is well for us to remember that the plant is first of all a structure, whose complexity may well challenge the most acute minds. We find it far easier to record the responses of plants to our planned stimuli than to unravel a structural complex, and so no doubt we shall continue to entertain ourselves and our students with what are too often futile experiments.

In this part of the botanical field are pathology, which grew up from our observation that organs may not respond normally; ecology, which developed from the observation that plants tend to live in communities; and phytogeography, having to do with the means for and the results of distribution. There are signs that for economic reasons pathology may become rather sharply set off from physiology, of which it is properly a part, much as through the zeal and enthusiasm of the ecologists there was once the suggestion of a physiological schism. The latter is happily no longer imminent, and it may be hoped that it will not again threaten the unity of plant physiology. And so it may be hoped that the pathologists will not wholly secede from association with the physiologists.

Taxonomy, or as we used to call it, classification, occupying the third division of the field of botany, long received the almost exclusive attention of botanists. And even to-day it is the pretty general opinion of our non-botanical friends that we are constantly employed in collecting specimens, and in some intricate and mysterious way determining their classification and affix-

ing to them their proper Latin names. And it must be admitted that every botanist does a good deal of just such work, quite as every chemist makes many analyses, and tries to arrange in orderly sequence the chemical substances which he has in his cabinet, and the astronomer classifies and names the heavenly bodies with which his science deals. At first even the botanists knew but few plants, just as now most men know scarcely more than a score. But as the botanists came to know a larger number of plants, it was imperative that they should be named, and then grouped conveniently for easier reference. Thus arose such crude, primitive classes as herbs, shrubs and trees, which served their purpose until the numbers became too great again, when additional structural differences were brought in to help separate the large numbers into smaller groups. This was the earlier classification, based upon structure alone. It was taxonomy without doubt, and it was helpful, since it enabled us to arrange plants in an orderly fashion, but it ignored the fact that plants have ancestors, and that the plants of to-day are what they are through their inheritance of ancestral characters, accompanied by modifications peculiar to them alone. When, however, the doctrine of evolution came into botany it brought with it the idea of descent, and thereafter taxonomy included phylogeny. To-day the taxonomist is no longer content to stop with a knowledge of the structural differences between plants; he must know how this structure arose from that; he must know which is the primitive structure and which the derived. Phylogeny has so far entered into taxonomy that it has given new meaning to the work of the systematic botanist, and it is bringing into this department of the science something of the philosophical aspect which was nearly

wanting heretofore. That this must be the direction of the development of the taxonomy of the future is without question, and we may look confidently for a marked expansion and enlargement of the phyletic idea in botanical taxonomy.

And here I may pause for a moment to advert to a part of taxonomy with which some biologists have little patience, without good reason, as it seems to me. I refer to the matter of taxonomic nomenclature which has vexed the souls of many botanists, especially during the past one or two decades. However, since every science must have its nomenclature it is childish for us to wish to ignore it in botany. It is a part of the science, and we must give it consideration if we are to do our full duty. I have been surprised many times when men have spoken disparagingly of the whole matter of nomenclature, and of those who are giving time and effort to its stabilization. While it may be granted that not every botanist is in duty bound to help to settle questions of nomenclature, or even to take part in framing the general rules of procedure, it is the duty of every one to appreciate and encourage those who are so engaged. It has sometimes seemed to me as I have heard wholesale denunciations of nomenclature and nomenclaturists that instead of being botanists we are only cytologists, morphologists, physiologists, pathologists, ecologists.

This contempt for nomenclatural questions is symptomatic of a much-to-be-deprecated state of mind, quite too common among scientific men, especially those who have engaged in special lines of work. I believe in specialization in botany, but specialization should not degenerate into narrow bigotry. A wise man long ago admonished his friends in words which I am tempted to repeat here as most fitting:

But now they are many members, but one body. And the eye can not say to the hand "I have no need of thee"; or again the head to the feet, "I have no need of you." Nay, much rather, those members of the body which seem to be more feeble are necessary; and those parts of the body, which we think to be less honorable, upon these we bestow more abundant honor, and our uncomely parts have more abundant comeliness; whereas our comely parts have no need: but God tempered the body together, giving more abundant honor to that part which lacked, that there should be no schism in the body, but that the members should have the same care one for another.

Wiser words of counsel for the workers in different parts of the field of a science were never written, and I beseech you, my botanical brethren, to heed them, "that there should be no schism in the body" of botany.

*Personality of the Botanist.*—Quite easily the foregoing leads to a consideration of the personality of the botanist of the immediate future. What manner of man will he be? What will be his training? In other words, what will the future demand of the botanist? For it does not need argument to show that the men engaged in botanical work in the future will be developed and fashioned in response to the demands of the community.

If I interpret aright the movement of modern society as a whole, it is going to result in a demand for two things that by many are thought to be opposite and antagonistic—specialization and breadth. The first it will demand of its experts, the men who are set aside to solve particular problems for the community. In most cases these will be economic problems of immediate importance to the community, but there is no reason why in the most intelligent communities they should not be scientific problems, of more remote importance. No doubt there will be a demand for many such experts, each of whose tasks will be

restricted to but one problem. The only requirement laid upon these men will be that they can do the work to which they have been assigned, and the more restricted the problem the narrower may be the preparation of the expert. Such men will be demanded in increasing numbers by the scientific bureaus of the general government, by the state experiment stations and by large private establishments engaged in beet growing, cane growing, fruit growing, potato growing, hop growing, etc., and it will be the duty of the teachers of botany to produce an adequate supply of such botanical experts.

But while the community is certain to increase its demand for botanical experts we must not overlook the fact that with this demand will come another, much more imperative, for men of far greater breadth and depth of knowledge, who in addition to training the botanical experts of various kinds for the community, are able to bring the science as a whole before the youth of the land as a part of the scientific culture which modern society requires. These must be men of the broadest training; men whose sympathies are not bounded by the one science which they know, much less by one phase of botanical science; men who, knowing well their one science, know also much of the related sciences; men who in addition to a knowledge of science bring to their students and their community the results of that broader view which relates botany to the life and activities of the community. Such men bear the name of botanists worthily, and justify the contention of scientific men that science may contribute more than material good to the community. These are Lord Bacon's "Lamps," and "Interpreters of Nature."

And my vision is by no means unrealizable. Already among botanists there are those who measure up to this ideal.

Already there are those who to a wide and deep knowledge of plants add that breadth of culture that brings them into sympathetic relations with the company of scholars throughout the world. As I speak these words there will come to you the names of those of our number who are known and honored as botanists, but whose beneficent influence extends far beyond the limits of their science. And I am confident that this high standard, now reached by some, will be demanded for all by the community of the future. Such botanists will be the leaders of their students, guiding wisely their early steps in science; they will be the leaders of the experts whose results they will be able to relate to other parts of the botanical field; and they will be the leaders of the community, not only in the applications of botany to the solution of material problems, but in a larger and nobler manner they will be able to help them in the higher things that make for culture and spiritual uplift.

*The Teaching Institutions.*—Turning now to the institutions of learning—the colleges and universities—where botany holds a place as one of the sciences, let us ask what we may look for in regard to its development. In every proper college the department of botany exists primarily for its teaching function, and this is true also for nearly every university. And while we may hope to make every such department a center of investigation also, it is true now, and it must always be true that in our educational institutions the teaching of the science must be the primary object of every one of its scientific departments. So the future will call for much more of definiteness as to the content and sequence of the science, as well as the manner of its presentation; its pedagogies, if you please.

The college and university departments of botany in the near future will arrive at

a clearer notion as to the essentials of the science as a subject of study. It seems to one who carefully looks over the field that there is often only the most vague notion of the relative importance of the known facts in regard to plants, those of trivial importance receiving as much weight, perhaps, as those of profound significance. Especially is this true of the more elementary courses, in which there is also the greatest diversity in the presentation of the subject matter. This condition argues incompleteness of knowledge either as to the science as a whole, or as to its pedagogics. We have all heard the excusatory remark that "it makes little difference how or where we begin the study of plants, and in what sequence we pursue it." Yet none of us would admit such a contention in regard to any other matter. The more we know of a country, the more definite are our ideas as to what are its more important mountains, rivers, cities and institutions, and it is these that we feel the traveler should see. We particularize when we know; we generalize, and are vague, when we do not. It should not be long until this vagueness and doubtfulness as to substance and manner in the presentation of botany in the high school, and in the college, and in the university, will be a thing of the past. In the near future we shall certainly have the lower work clearly defined, as it is in mathematics and language, and on this the higher work will be based, to the great saving of the time and energy of teacher and student, now needlessly wasted. And I appeal to you, botanists, to take up seriously the task of so arranging and coordinating our work that botany shall no longer suffer the reproach of being the most chaotic of the primary sciences. Do not tell me that we can not agree. *We must agree.* If we know our science sufficiently well we can easily discern the more important parts. Let him

whose knowledge is too limited to enable him to see over the whole field step aside. Let him who has no adequate perception of the pedagogical aspects of the problem step aside. Then let the select few make a pronouncement, subject to periodical revision. This is the way that scientific men should settle the question. This is the way it will be settled some day, in the not very distant future.

*The Botanical Stations.*—But the college and university departments are by no means all that are engaged in botanical work. Within the past twenty-five years many stations have arisen in which botanical investigations are made. Under various local names they are in fact "investigation stations" and while their results have not been uniformly reliable it is a most hopeful sign of progress that they exist at all. Foremost among these are the fifty or more agricultural experiment stations to which I have already briefly referred, with assured support from the states and the national government for all time to come, in which botanical investigation forms no inconsiderable part of the work undertaken. Hampered as they generally were in their earlier years by incompetent direction, and often by still more incompetent workers, it is gratifying to know that year by year there has been marked improvement in both, and that now many of the directors are men of such scientific training that they wisely use the means at their disposal for investigations of permanent scientific value. And if I read aright the tendencies in these stations, it will not be long until their scientific output will be wholly reliable, as indeed it is now in some cases. This condition will be fully realized when these stations are wholly under the direction of men of broad scientific training.

And here again we have a duty to perform. We must recognize the agricultural

experiment stations as permanent parts of the botanical equipment of the country. They will be with us in the future, and their results will continue to be added to botanical knowledge. We must accept them as a part of our scientific equipment, and help to make them more efficient. It will not do for us to stand aloof, and deery their results as not accurate, and as agricultural instead of botanical. When we fully realize that we have in these experiment stations so many institutions of endowed research, we shall not hesitate to welcome them to the ranks of science. The fact that these researches in regard to plants so often have an economic purpose does not lessen the value of the results to the botanist of broad training and sympathies. Here again we must remember that as botanists we should not undervalue those contributions to knowledge in which we happen not to have an immediate interest. My scriptural quotation of a few minutes ago might well be repeated here: "the eye can not say to the hand 'I have no need of thee,' or again the head to the feet 'I have no need of you.' " When they receive the hearty cooperation of the botanists of the country the agricultural experiment stations will develop into centers of investigation of the greatest importance to science.

Already we have stations for the study of plants under particular environments, as our seaside stations, our mountain stations and a single desert station. I take it that these are suggestive of what are to come in the future. Instead of trying to make seaside conditions away from the sea, we go to the sea and there set up our laboratories. So when we want to know how plants behave in the desert we go to the desert. And this is no doubt to be the direction of botanical investigation. We are going to study plants under their natural environ-

ment, and to the seaside laboratories we shall add (as indeed we have already to a limited extent) lakeside laboratories, riverside laboratories, swamp laboratories, forest laboratories, field laboratories. Already the tropical laboratories, in Java, Ceylon and Jamaica have justified themselves, and no doubt to these we shall soon add arctic and tundra laboratories. All this signifies that more and more we are going to see what the plant is doing in its natural environment, and then we can undertake intelligently to watch it under a changed environment. So the future is to witness a great increase in the number of these laboratories, and how far it will go can only be conjectured. It now appears probable that eventually every botanical department will have one or more of these environmental laboratories in which work may be done by advanced students. They will take the students out of doors, as the old-time systematic botany took them out, but these students will go equipped with thermometers, psychrometers, anemometers and balances, instead of vascula and plant presses. Thus we shall again go afield, but on what a different quest! The old-time botanist in the field was mainly concerned with the question of the specific identity of each plant he found; the botanist afield in the future will ask what the plants are doing under this or that environment. He will not neglect the earlier question, in fact he must have that answered, but that answered he has still his main question before him. The work in the field laboratories must necessarily be of the kind now called ecological, and so as I see it the botany of the future will have much more of ecology than is common to-day.

Yet when we think of these botanical stations whose laboratories are taken afield, as it were, we must not suppose for a moment that the old-time laboratories on the uni-

versity campus are to be abandoned. Far from it. As the work in the field laboratories is enlarged there will be still greater need of the far more exact work that can be done only in laboratories where every factor can be perfectly controlled. There will still be need, greater need I might say, for perfectly constructed plant-houses in which we may observe plants under controlled conditions, and where we may increase or decrease this or that factor at will. I emphasize this point because there are some who prophesy the eventual abandonment of the precision laboratory in botany, when in fact everything points to the opposite conclusion.

Another kind of station, of which we have now only the beginnings, is one which will carry the results of plant breeding into the domain of phylogeny. Of this we have now some faint suggestions, which must grow into far reaching results under the direction of men who know more of the subject than we do now. It may be that such stations will then, as now, have a strong economic bias, but this will not so narrow them as to exclude the phylogenetic aspects of the work they are doing. In such laboratories we shall be able to see how evolution has contributed to the present wonderful diversity of form and size and color and habit among related plants. Such laboratories will enable us to answer the demand formerly so often made, but less often heard now, for a demonstration of cases of actual evolution. Although such cases are well known to botanists, their occurrence has hitherto not been such as to admit of easy citation for purposes of popular demonstration. So I regard the breeding laboratories of the future as welcome additions to the means of demonstration which science will possess.

*Unity of Action.*—Allow me to look once more into that future which holds so much

of promise for botany. I am assured as I consider the trend of scientific thought that there will be greater unity of action among the botanists of the country. At present we are still in the guerrilla stage of botany, in which every man acts independently and for himself. And it must be admitted that much effective work is done by guerrillas in war and in science, but in both there is far too much waste of energy. Let me pause a moment to explain more fully what I mean by this guerrilla condition in botany. Although we profess to be botanists acting for the best interests of science, we have actually no uniform standard by which we may measure our actions. In one particular we have tried to set up a standard, in certain international rules pertaining to nomenclature: and yet after several congresses of botanists we have the humiliating spectacle of a set of laws that nearly everybody disobeys! In other matters also, every man does as he pleases; and the worst of it is that he vehemently defends this free, untrammelled mode of action. We have been guerrillas so long that we resent the suggestion of conformity to any regulation.

Brethren of the ancient order of botanists, this is scientifically quite unseemly. We must cease this personally independent, but disorderly life, and enroll ourselves in the regular army as good soldiers who will obey orders, and who will act in unison for the common good. And this is no illusory vision. It is one of the things that the future will bring us, yes, I may say, is bringing us. For already we find the beginnings of a reduction of some of the disorder in certain fields of work. In the management of the work of the agricultural experiment stations there are hopeful signs of a healthy progress. Certain officers in Washington, having general supervision over the stations, seeing that there is much useless

duplication, have begun suggesting more harmonious planning, one station to emphasize this line of investigation, and another that line, instead of working quite independently of one another. This beginning is suggestive of what might and should be done elsewhere.

And we shall not confine unification and coordination to investigation alone, but will carry it into the teaching departments. As a matter of course the more general aspects of the science must find place in every college department of botany, requiring to this extent the quite legitimate duplication of the best laboratory and other facilities that can be provided. But beyond this the duplication should cease, especially of facilities that are costly in installation and maintenance. When we fully reach a condition of scientific sanity we shall agree upon such a program as will assign particular fields of work to those institutions that are best able to care for them, and it follows that students will be sent to these for such specialties. In the case of the state institutions there is already the beginning of the attempt to reduce needless duplication—in some instances crudely and awkwardly, it is true—but the significant thing is that there is already an attempt to reduce duplication. Which suggests that “the children of this world are in their generation wiser than the children of light.”

This is not the place for the discussion of the details of the educational cooperation which is coming—a cooperation which will result in a conservation of educational energy. As the details are needed they will be worked out, but I may be permitted to suggest that in the near future we shall reach a solution something like the following:

(a) That the small colleges shall provide a standard course in general botany, with adequate facilities as to material and apparatus.

(b) That the larger colleges and universities shall provide an identical standard course for those of its students who have not pursued this subject in the small colleges, and to this they will add certain advanced, also standardized, courses, requiring facilities beyond the reach of the small colleges.

(c) Then will come, especially in the state-supported schools, such advanced courses as are required by the nature of the institutions, and the needs of each particular state; as the study of useful plants, noxious plants, local systematic botany, dendrology, pathology, etc.

(d) Last will come a division of labor with regard to the more profound lines of research and teaching. Certain favored institutions will place especial emphasis upon minute anatomy (cytology and histology), or special morphology, or physiology, or plant breeding, or ecology, or phytogeography, or special taxonomy, or general and experimental evolution, or botanical history, etc.

These suggestions are not chimerical. They are indicated by the recent trend of scientific thought, which recognizes more and more the value of the conservation of human effort. And as I look into the future a vision rises before me of the scientific army, working harmoniously like well-drilled soldiers, and not wasting their strength by turning their guns on one another. In this army of science I see a company of thoroughly disciplined botanists who in orderly fashion plan their campaign. And, from the many doing severe garrison duty in the small colleges, to the heavy artillerymen in the big university fortifications, and the few isolated scouts along the frontier of special investigation, all are actuated by a common spirit of scientific patriotism and loyalty.

This, my botanical brothers, is what the

future is bringing us—a united, harmonious body of trained men, whose endeavor is to carry forward the banner of science, not for personal advantage, but for the glory of the science to which we have dedicated our lives.

CHARLES E. BESSEY

#### RECENT EXPLORATIONS IN SIBERIA

ACCORDING to recent information received from the American Consul at Vladivostok (transmitted to the Dept. of State, Sept. 10, 1912), and from other sources the following scientific exploration has been carried on during the current year in the Russian far east:

An important work was carried on in Siberia by the Russian Geological expeditions sent out to look for new gold deposits. The Russian Mining Department had expeditions in the Bargusin district on the Zeia River, in Minusinsk and in Kamchatka. The Russian Mineralogical Society was studying Lake Ingel in the Achinsk district. The Russian Geological Society has also begun an extensive study of the Kalbin Mountains in the Ust-Kamennogorsk district on the left bank of the river Irtysh, where three independent parties are working at present. A Russian Gold Mining Company is studying the river Kolba, for which purpose three professors of the Tomsk University have been engaged. The Russian Geological Society has also sent out an expedition to study the country on the river Yenisei from Krasnoyarsk down to Dixon Island, situated in the Arctic Sea about two miles from the mouth of the Yenisei River. The purposes of this expedition are the study of the magnetism of the earth, and the definition of the astronomical coordinates for the northern sea route. An auxiliary motor schooner has been sent to the village Dudinskoe to serve as a temporary magnetic laboratory. The Yenisei River will also be studied from a botanical point of view, and the fish resources of the river are to be investigated.

The director of the Irkutsk Laboratory is making magnetic observations on the Lena River down to its estuary, where the region of the maximum magnetic force is located. The Colonization Department is making studies of the flora and soil in the Semiretchie, Barabinskaiia Steppes in Kainsk and Mariynsk districts and in Akmolinsk Province.

The Russian Society for the Study of Asia is investigating the unknown ruins on the right bank of the river Obi in the Barnaul district. Bones of animals and birds, stone and bone weapons and articles of bronze and copper have been found, as well as some fragments of pottery with ornaments belonging to an old civilization.

Dr. A. Hrdlicka, of the United States National Museum, has been engaged in anthropological exploration along the upper Yenisei River, on the Selenga, and in northern Mongolia.

The Altai is attracting special interest and several well equipped expeditions are working there on various lines.

Siberia, and especially the Russian Far East, seem to attract a great deal of attention in Europe. The French Department of Education, the Geographical Society and the Museum of Natural and Historical Knowledge have sent Daniel Busson with assistants to Siberia to prepare ethnographical, anthropological and natural history collections, as well as to take photographs and moving pictures. From Irkutsk they are to go to the Transbaikalia, and from there to Yakutsk by the Lena River and from the river Kolima to Vladivostok. Much interest is manifested in scientific circles, as well as by students of economics, in regard to this almost unexplored and unexploited country which is so rich in opportunity for the seeker after truth.

Professor George Mixer, of Boston, has recently concluded a successful scientific expedition and hunting trip in the vicinity of Lake Baikal under the auspices of the Smithsonian Institution, Washington.

A Russian expedition has been sent out from St. Petersburg to examine the coasts of the Okhotsk Sea, the valley of the Anadir River close to Behring Straits, and the Gischiti and Aldon valleys. The chief of the expedition is Mr. P. I. Polevoi, a learned geologist and mining engineer, who is accompanied by topographers of the army.

It is further reported that the following expeditions have or will also visit Siberia:

1. An expedition to the Altai Mountains by Professor Lyman and Mr. Hollister for the purpose of making a collection of plants and animals for the United States National Museum and Harvard University.

2. Dr. Stanislav Hanzlik, professor of Prague University, to make a study of climatical and meteorological conditions of the Russian Far East.

3. Sven Johan Ernander, a Swedish explorer, to make a botanical study of western Siberia.

It should also be remarked that the matter of perfecting the northern route from Vladivostok to European ports via Behring Straits (so successfully navigated last year from Europe as far as the Yenisei River by the English navigator, Captain Webster, and from Vladivostok to Kolima River by a Russian vessel), and the charting of the new uncharted coast lines in many places on this route, is receiving attention from a special Russian expedition which sailed from Vladivostok at the opening of navigation this year. They will winter in the Arctic Sea and proceed next year on their voyage.

#### A. HRDLIČKA

#### THE REORGANIZATION OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF CALIFORNIA

At a meeting of the regents of the University of California in December, 1911, the Committee on Medical Instruction recommended that the departments of the Medical School in Berkeley and San Francisco be brought together in San Francisco as soon as possible, that the clinical years be put upon an academic basis, and that a proper teaching hospital and proper laboratories be provided in order to promote the best interests of the university as a whole, and of the Medical School in particular. It was declared the desire of the board to establish a medical school of the highest standard.

At a meeting in April, 1912, upon the recommendation of the Medical Faculty, the following plan of reorganization was adopted. Clinical instruction in the medical school is to be carried on in three main departments. (1) Gynecology and obstetrics: it was decided to put this department upon an academic basis at once and to allot full academic salaries for a professor and an assistant. (2) Medicine: this department to include pediatrics, neurology and dermatology. This department can not as yet be placed upon a full academic basis, but \$2,300 has been devoted to the payment of assistants for the current year. (3) Surgery: this department to include orthopedics, urology, ophthalmology, rhinology, otology

and laryngology. As with medicine, there were not sufficient funds available this year to put the department upon a full academic basis, but \$1,800 was devoted toward paying three assistants.

In addition to the main departments, the work of the hospital pathologist was reorganized and an additional assistant professor of pathology was secured at a salary of \$2,400 a year. It was voted to grant \$1,200 for the work in radiography.

The budget voted to medicine 1912-13, for maintenance of the first two years, was:

	Salaries	Budgets	Total
Anatomy .....	\$11,500	\$3,555	\$15,055
Physiology and physiological chemistry ..	8,120	3,000	11,120
Pathology and bacteriology .....	9,900	3,800	13,700
Toward academic instruction in the clinical years .....			12,000
For additional expenses of the clinical years:			
General budget .....			7,630
Special budget for university hospital			6,480
Assistant superintendent and hospital stenographer .....			2,400
Deficit .....			12,000
Total for medical instruction .....			80,385

In accordance with the plans adopted by the regents, a movement is on foot to provide a new university hospital. The present plans aim at four units of forty to fifty beds each, to be devoted respectively to surgery, medicine, diseases of women and diseases of children. Money has already been given (\$350,000) by private individuals to build and equip the departments of medicine and children's diseases. In order to carry on the work in the present buildings, the regents have granted \$14,000 for alterations in the hospital for accommodation of clinics, and \$6,000 for equipment of clinical and pathological laboratories. A children's ward has been added to the hospital.

#### SCIENTIFIC NOTES AND NEWS

The following have been elected corresponding members of the Munich Academy of Sciences: Dr. Otto Struve, professor of astron-

omy at Berlin; Dr. Mittag-Loeffler, professor of mathematics at Stockholm; Dr. H. A. Schwarz, professor of mathematics at Berlin; Dr. Walther Nernst, professor of physical chemistry at Berlin; Dr. Sigismond Exner, professor of physiology at Vienna; Professor A. G. Nathorst, director of the Paleontological Museum at Stockholm, and Mr. Bailey Willis, of the U. S. Geological Survey.

DR. H. A. LORENTZ, professor of physics at Leiden, has been made an honorary member, and Dr. Ernest Rutherford, professor of physics at Manchester, and Dr. W. C. Brögger, professor of geology at Christiania, have been made corresponding members, of the Vienna Academy of Sciences.

THE honorary degree of D.C.L. has been conferred on Sir William Osler, regius professor of medicine at Oxford by Durham University.

THE Paris Academy of Sciences has awarded its Binoux prize (for the history of science) to Professor J. L. Heiberg, of the University of Copenhagen, for his works on the history of ancient mathematics and in particular for those on the method of Archimedes.

DIRECTOR BAILEY has been appointed to represent Cornell University at the inauguration of Dr. C. A. Duniway as president of the University of Wyoming on January 24. Besides making a speech at the inauguration, Mr. Bailey will make an address on the occasion of the laying of the corner stone of Wyoming's new agricultural building.

ON the evening of December 17, the Linnean Society of New York held its first annual banquet at which Mr. Frank M. Chapman was the guest of honor. The occasion had the twofold object of inaugurating a series of annual dinners and of honoring Mr. Chapman for his distinguished services to ornithology. Dr. Jonathan Dwight, Jr., president of the society, acted as toastmaster, and among other guests at the speaker's table besides Mr. Chapman were Dr. Henry Fairfield Osborn, Mr. John Burroughs, Dr. A. K. Fisher, Mr. George Bird Grinnell, Mr. T. Gilbert Pearson, Dr. Fred-

eric A. Lucas, Mr. Spencer Trotter, Mr. Ernest T. Seaton and Mr. John H. Sage.

PROFESSOR H. J. WHEELER, for the past ten years director of the Agricultural Experiment Station of the Rhode Island State College, who recently resigned, has accepted the position as manager of the Agricultural Service Bureau of the American Agricultural Chemical Company of Boston and New York, with headquarters at 92 State St., Boston, Mass.

MR. BENJAMIN BOSS has been appointed acting editor of the *Astronomical Journal*.

MR. H. D. GOODALE has recently been appointed by the trustees of the Massachusetts Agricultural College as research biologist in the department of poultry husbandry of the experiment station. Mr. Goodale graduated from Trinity College in 1903; after spending a year in graduate work at that institution, he spent three years at Columbia University as a special student of zoology. From 1907 to 1911 he was engaged in farming, and since 1911 has been employed by the Carnegie Institution of Washington in its department of experimental evolution.

THE cornerstone of the new dispensary building of the College of Medicine of Syracuse University was laid on December 14 by Chancellor Day. Afterwards addresses were made by Dr. William S. Thayer, of the Johns Hopkins University; Mr. Augustus S. Downing, assistant commissioner of education of the state of New York, and Mr. Alan C. Forbes, who spoke on behalf of the Syracuse Free Dispensary Association.

PROFESSOR MARSTON TAYLOR BOGERT, of the department of chemistry, Columbia University, president of the Society of Chemical Industry, lectured on December 16, before the McGill Chemical Society, Montreal, on the subject of "The Classification of Carbon Compounds," and in the evening addressed the Montreal members of the Society of Chemical Industry at a banquet at Coopers Limited. On the following day he addressed the Toronto members of the society at a banquet at the Engineers' Club, Toronto, on the subject of "A Closer Cooperation between the Universities and Chemical Industries."

DR. E. V. FARWELL, associate professor in the department of chemistry of the college of agriculture of the University of Wisconsin, lectured to the students of the department of chemistry, on December 18, on "The Rôle of Mineral Elements in Nutrition."

DR. E. P. LYON, of St. Louis University School of Medicine, recently delivered the Founders Day address at the Bradley Polytechnic Institute, Peoria, Ill., on the subject, "Medicine and Engineering."

MR. AUSTEN CHAMBERLAIN will preside at a meeting at the Royal Colonial Institute, London, on January 14, in support of the fund he is raising for the extension and development of the London School of Tropical Medicine, when Sir Ronald Ross will give an address on the work of the school and the advantages of tropical medicine.

CERTAIN geological works of Dr. Alexander Winchell, former professor of geology at the University of Michigan, have recently been found at the state capitol at Lansing, where they have been kept since Dr. Winchell's death forty years ago. Over four hundred works are included in the collection, which is a very valuable one, including plates and hand drawings. The works are the property of the Michigan State Geological and Biological Survey, and will be published in an appropriate form.

THE valuable collection of microscopic slides and preparations left by the late Professor T. H. Montgomery, Jr., have been given by Mrs. Montgomery to the zoological department of the University of Pennsylvania. The collection comprises upward of 3,800 mounted pieces and slides, in addition to a large number of objects embedded in paraffin.

MR. WILLIAM B. TEGETMEIER, the distinguished English naturalist, known for his work on pigeons and other animals and for his cooperation with Charles Darwin in the study of variation, has died in his ninety-seventh year.

MR. CHESTER A. REED, curator of the Worcester Natural History Society and the author of several books on bird life, died at Worcester on December 16.

MR. EUGENE SMITH, a Brooklyn engineer, interested in natural science and editor of *The Aquarium*, died on December 25, aged fifty-two years.

DR. ERNST VON KOKEN, professor of geology at Tübingen, has died at the age of fifty-two years.

DR. WILHELM FIEDLER, formerly professor of mathematics in the Zurich Technical School, has died at the age of eighty years.

M. AIMÉ PAGNOUL, formerly director of the Agricultural Station at Pas-de-Calais, has died at the age of ninety years.

THE examination for the position of curator of the State Natural History Museum of Illinois, recently mentioned in these columns, has been postponed by the civil service commission until January 25, in order to secure more applicants. This is a position which pays \$3,000 per year. Applications should be on file in the office of the state Civil Service Commission, Springfield, Ill., not later than January 18.

THE next meeting of the International Union for Solar Research will take place at Bonn beginning August 1, 1913.

AN international congress for physical education will be held in Paris, March 17-20, 1913, under the auspices of the faculty of medicine. It is expected that the United States will be represented.

IN view of the seventeenth International Congress of Medicine, which is to take place in London in 1913, a committee has been formed for the purpose of organizing a museum, and Professor Arthur Keith, conservator of the Royal College of Surgeons' Museum, has been chosen chairman. Accommodation has been secured at the Imperial College of Science, South Kensington, and the museum will be arranged in this place as far as is possible in correspondence with the sections of the congress. It has been decided that, as the meeting is to take place in London, and as the visitors will doubtless desire to inspect the metropolitan hospitals and other great institutions, material will not be collected from the museums of the metropolis. The committee

are therefore seeking exhibits from provincial institutions and from private collections.

It is stated in the British *Geographical Magazine* that the Paris Society of Natural Sciences has succeeded in making all arrangements for the establishment of a magnificent national park, of which an account was given by Dr. Paul Sarasin at the September meeting of the society at Altdorf. The park is situated in the canton Grisons, in the lower valley of the Inn, near Zernetz, and consists meantime of an uninterrupted stretch of land about forty square miles in extent, which it is hoped later to increase to nearly eighty square miles. All this vast territory will be wholly withdrawn from human interference, and set aside as a biological preserve. It contains at present chamois, a few bears, and a rich flora. Some paths are to be made, together with blockhouses to suppress poaching, and regular observations will be undertaken. Part of the territory has been leased for twenty-five years, and the rest for ninety-nine years, and the cost of rent, surveillance, and observations are to be defrayed out of the funds supplied by a popular league, with a very low annual subscription.

It will be remembered that at the Dundee meeting of the British Association in September last the president of the Zoological Section, Dr. P. Chalmers Mitchell, F.R.S., took as the subject of his address "The Preservation of Fauna." At the close of the meeting the general committee passed on to the council, for consideration, a resolution, which has now been adopted in the following terms:

That the British Association for the Advancement of Science deplores the rapid destruction of fauna and flora throughout the world, and regards it as an urgent duty that steps should be taken, by the formation of suitably placed reserves, or otherwise, to secure the preservation of examples of all species of animals and plants, irrespective of their economic or sporting value, except in cases where it has been clearly proved that the preservation of particular organisms, even in restricted numbers and places, is a menace to human welfare.

THE thirtieth expedition of the Liverpool School of Tropical Medicine, under Dr.

Harald Seidelin, of the Yellow Fever Bureau of the school, sailed from Southampton for Jamaica on December 17. The main object of the expedition is to investigate the disease called "vomiting sickness," which is often fatal to children. The expedition has been promised the support of the English government and of the government of Jamaica.

THE Ohio Academy of Science held a successful meeting at the Ohio State University from November 28 to 30, 1912. The program contained about fifty papers on various subjects in the fields of zoology, botany, geology and physics. The physicists organized a new section in the academy during the past year and participated in the program of this annual meeting for the first time. Eleven papers on various subjects in physics were presented. Mr. Emerson McMillin, of New York, renewed his annual donation of \$250 for research work to be conducted under the auspices of the academy. This gift has been continued for a number of years and has been the means of assisting a large number of important scientific investigations. The Biological Survey of Ohio, which was organized during the past year through the cooperation of the Ohio State University and fourteen other colleges of the state, was heartily commended by resolution and the earnest support of the academy was pledged to the undertaking. Another resolution of importance adopted by the academy was one calling for legislation by the state to prevent the propagation of the feeble-minded, insane and habitual criminal. Professor L. B. Walton, of Kenyon College, Gambier, and Professor E. L. Rice, of Ohio Wesleyan University, Delaware, were elected president and secretary, respectively, for the coming year.

THE University of Minnesota is offering a series of lectures upon "Modern Developments in Science." These lectures are given by members of the regular staff of instruction, on Wednesday evenings, in the chemistry building. The program of the series follows:

November 13—"Practical Applications of the Gyroscope," Assistant Professor B. L. Newkirk.

November 20—"Comets I have Known," Professor F. P. Leavenworth.

November 27—"Thunder and Lightning," Professor John Zeleny.

December 4—"Radium, its use in Physics and Medicine," Assistant Professor Alois F. Kovarik.

December 11—"Electrical Transmission of Intelligence," Professor G. D. Shepardson.

December 18—"Some Advances in Modern Bridge Engineering," Professor Frank H. Constand.

January 15—"The Air We Breathe," Dean George B. Frankforter.

January 22—"A Geological Exploration in Southwest Colorado," Professor W. H. Emmons.

January 29—"American Metal Mining," Professor Chas. E. van Barneveld.

February 5—"Geographical Studies in Glacier National Park," Assistant Professor E. M. Lehnerts.

February 19—"The Influence of the Study of Fossils—Paleontology," Assistant Professor F. W. Sardeson.

February 26—"Heredity and Eugenics," Professor H. F. Nachtrieb.

March 5—"Plants and the Cost of Living," Professor F. E. Clements.

March 12—"Sickness in Plants—Causes and Remedies," Professor E. M. Freeman.

March 19—"Modern Warfare against Grasshoppers; and Protective Coloration and Mimicry of Insects," Professor F. L. Washburn.

April 2—"Some Recent Developments in the Study of the Nervous System," Professor J. B. Johnston.

April 9—"The Special Child," Professor J. B. Miner.

April 16—"Recent Progress in the Study and Cure of Cancer," Dr. H. E. Robertson.

April 23—"Modern Surgery," Dr. A. T. Mann.

April 30—"The Two Most Important Epochs in the History of Modern Medicine: the Discovery of Vaccination and the Discovery of the Relation of Microorganisms to Disease and the Application of the Antiseptic Principle to the Practice of Surgery," Dr. Burnside Foster.

May 7—"Living with Head Hunters," Professor Albert E. Jenks.

We learn from the *Geographical Journal* that the attention directed of late years to the antiquarian remains at Tiahuanacu has led the Bolivian Minister of Public Instruction,

at the instance of Señor Ballivián, to provide funds for the systematic excavation of the site of the ruins, with a view to saving them from further depredations of a kind to which they have been subject in the past. The work has been carried out under the supervision of the director of the National Museum, Dr. Otto Buchtien, and a report on the results so far gained has been circulated by Señor Ballivián. At a depth of from 3 to 10 feet below the surface a large quantity of pottery was found, of pre-Inca age, many of the objects being in a perfect state of preservation. They at once rivet the attention by the fineness of the material, and in the case of the cups, bowls, etc., by their artistic form as well as by the excellence and freshness of the coloring. The diversity of the ideographs and pictographs represented on them will demand special study by experts. Among the smaller objects, a human figure in silver is interesting as showing the nature of the garments worn in that ancient time. Worked stones have also been found, and skulls showing distinct traces of deformation. One of the latest discoveries had been a skull, belonging apparently to an ancient race, and showing the frontal suture and larger in all its dimensions than skulls of the present day. Further reports are promised as the work progresses.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE Hamburg senate has adopted the proposal to found a university there consisting of three faculties—law, philosophy and colonial science. These are to be supported by the interest on \$6,250,000, which has been appropriated for the purpose by the city.

THE program for the exercises at the dedication of Lincoln Hall, University of Illinois, to be held on February 12, includes addresses by Mr. Hugh Black, Governor Deneen and Bishop McDowell of Chicago. Lincoln Hall was made possible by an appropriation of \$250,000 by the legislature in 1909, the one hundredth anniversary of Lincoln's birth and it was decided to give the building its present name and dedicate it to the study of humanities.

DR. BURT L. HARTWELL, professor of agricultural chemistry in the Rhode Island State College, has been appointed director of the station to succeed Dr. Homer H. Wheeler, who recently resigned.

MR. E. G. ARZBERGER, H. R. Watts, J. B. Demaree, L. E. Melchers and J. T. Rogers, assistant botanists in the botanical department of the Ohio Agricultural Experiment Station, have resigned from their positions.

DR. J. W. NICHOLSON, M.A., Trinity College, Cambridge, has been appointed professor of mathematics in London University, being attached to King's College.

DR. W. H. PERKIN, F.R.S., professor of chemistry at Manchester University, has been elected Waynflete professor of chemistry at Oxford. A grant of £15,000 towards the erection of the new chemical laboratory, as well as a further loan, has been promised by the trustees of the chancellor's endowment fund.

#### DISCUSSION AND CORRESPONDENCE

##### A NEW WEED EXTERMINATOR

WILD garlic (*Allium vineale*) has become a serious farm pest, especially in the belt of territory extending from Maryland to Missouri. Beside having the usual competitive action as a weed in cultivated fields, the presence of bulblets in wheat lowers the market value, as the bulblets are about the size and color of the grains, and difficult to separate. The weed also gives an unpleasant taint to the milk and flesh of animals feeding on the leaves, and to flour made from wheat containing the bulblets.

Owing to the remarkable tenacity of life possessed by the bulbs and bulblets no practical method to rid the soil of the pest has heretofore been found, and in some localities fields have been abandoned and given over to the weed.

Nearly two years ago an investigation of the wild garlic was taken up as a special problem by the Botanical Department of the Indiana Experiment Station. The field tests were carried on in cooperation with Dr. H. E. Horton, agronomist of the American Steel & Wire Co.,

and Mr. Jacob Cronbach, of Mount Vernon, Ind. After various chemical sprays and cultural methods had been tried to little purpose, Mr. F. J. Pipal, assistant botanist in the Indiana Station and in direct charge of the work, suggested the use of orchard heating oil, as supplied by the Standard Oil Co., applied as a spray.

Remarkable results were obtained from the beginning of the tests. It was found that when the oil was distributed over the field in a fine spray by a sufficiently powerful spraying machine, that all growing vegetation was killed, not only above ground but below ground as well, except the long horizontal rootstocks of such plants as *Tecoma radicans* and *Solanum carolinense*, and the extra large roots of such plants as *Ipomœa pandurata*, the latter requiring a correspondingly larger amount of oil. It destroyed the bulbs of the wild garlic, however deep below the surface, and the bulblets at the tops of the stalks as well. The oil appeared to produce no lasting effects upon the soil, and new growth from seeds already in the soil and from subsequently sowed cereals possessed the usual vigor. The best times and methods for the application are now being tested.

The introduction of this new material for killing weeds is accompanied by a new method of application. Heretofore chemical sprays have been differential, and intended to kill only the weeds while leaving the crops essentially unharmed. Orchard heating oil acts as a complete spray, killing all vegetation, like plowing or fire, only more effectively than these, as it follows the stems and roots well into the ground.

INDIANA EXPERIMENT STATION,  
PURDUE UNIVERSITY

##### GREEK REFINEMENTS IN ARCHITECTURE

THE existence of subtleties of line and spacing in Greek architecture is now well known. A very interesting point is how much of the classic practise was lost in the Dark Ages and how much preserved. The following extract from "Evelyn's Diary" seems to bear upon the point. It shows, at least, that

similar problems were familiar to English architects of the seventeenth century.

1666, Aug. 27, I went to St. Paule's church, where with Dr. Wren, Mr. Prat, Mr. May, Mr. Thos. Chichley, Mr. Slingsby, the Bishop of London, the Deane of St. Paule's and several expert workmen, we went about to survey the general decays of that ancient and venerable church, and to set downe in writing the particulars of what was fit to be don, with the charge thereof, giving our opinion from article to article. Finding the maine building to recede outwards, it was the opinion of Mr. Chichley and Mr. Prat that it had been so built *ab origine* for an effect in perspective, in regard of the height; but I was, with Dr. Wren, quite of another judgment, and so we entered it; we plumb'd the uprights in severall places. . . . (From Evelyn's Diary.)

EDWARD S. HOLDEN

WEST POINT, N. Y.,

November, 1912

#### THE QUESTION OF THE OLDER AND NEWER APPALACHIANS

In a lucid and valuable article on the geography of the United States, Professor Wm. M. Davis divides the Appalachians<sup>1</sup> into an older eastern and a newer western belt. He makes in New England the Taconics and the great limestone valley the newer, and all the rest of New England from and including the Green Mountain range the older. By this he means composed mainly of older rocks.

The distinction is good, but the names should be reversed for New England.

The western division contains mainly Cambrian and Ordovician rocks. A narrow interrupted band of Archean forms the west border of the eastern band, going south from the Hoosac Tunnel. Next east is a band of the Hoosac and Rowe schists, which are correlated with the Berkshire schist of the western division and so are Ordovician. Next east is the much broader band of the "Calceiferous Mica Schist" (the Goshen and Conway schists), which extends to the Connecticut Valley, and widens northerly into Canada, carrying Silurian fossils. Next east is the

Bernardston Devonian, underlying the Connecticut Valley and in part covered by Trias. The whole of Worcester County is Carboniferous, cut by late Carboniferous granites. The new discovery of Carboniferous fossils in Worcester by David White reinforces Perry's earlier finds, and all the Carboniferous rock types occur in the eastern rim of the Connecticut Valley, and all the intervening country can be connected by transitions with the undoubted Carboniferous.

East of Worcester is a narrow seaward band of Algonkian and Cambrian greatly covered by Carboniferous, so that about nine tenths of the area between the Housatonic Valley and the sea is covered by rocks newer than those of this valley and the Taconics.

This change of name does not lessen the great value of the distinction, which is based not so much on age as on the presence of the great limestone in the western belt and its lesser metamorphism, which has caused great differences in the topography. The lesser metamorphism of the western belt depends, in part, on the absence of granite which has overwhelmed all the area of the eastern belt. They have both been subjected to the same folding and uplifting agencies, but the overthrust faulting along the east border of the limestone valley has had for an effect that less and more varied pressure was transmitted westwardly, while the greater pressure in the east has not only caused greater metamorphism across central New England, but the extensive intrusion of various granites has greatly increased this metamorphism, and has left a country where a very broad meshed network of Carboniferous schists rests in great areas of carboniferous granite.

The eastern division, which has for its western border the Green and Hoosic Mountains, constitutes the New England Province, and, taken as a whole, has an interesting balanced arrangement. The ancient Green Mountain protaxis made up of Archean to Ordovician rocks is balanced on the east by the equally ancient Nova Scotian series, which is lithologically similar, and both are gold bearing.

Next inwardly the narrow fault bounded

<sup>1</sup> Mill's "International Geography," pp. 717-732.

Connecticut Valley depression with its Triassic traps and sandstones stands over against the similar narrow Triassic basin of the Bay of Fundy, continued in the Boston and Narragansett basins. There remains the broad central New England Plateau, made up of great late-Carboniferous granite batholiths running north and south, or with a little easting and isolated by bands, often very narrow, of late Paleozoic rocks, largely Carboniferous.

The series of batholiths in this central plateau is itself symmetrically arranged and becomes more basic from the center outwardly.

Crossing the center of the plateau from north to south is the broad Hubbardston-Princeton band of granite which is truncated by erosion so nearly along its contact with the cover of Carboniferous schists, that it is everywhere contaminated with the sillimanite and graphite of these schists, and is made coarsely pegmatitic from the water obtained from them.

Next on the east is the long train of oval batholiths running through Worcester, the Ayre series, which are of uniform porphyritic texture, and are matched on the west by the coarsely porphyritic Coy's Hill series, passing east of Ware.

Next outwardly the dark biotite Bolton granite-gneiss on the east is matched by the broad band of the black Hardwick biotite granite, passing through Ware.

Then follows on the east the fine-grained Milford biotite granite, so valuable as a building stone, which is comparable with the Monson and Pelham biotite granites on the west, which are also extensively quarried.

Finally, the complex Quincey-Dedham series of igneous rocks along the eastern border of the area, with its basic and soda-rich rocks, is balanced by the basic Belchertown series, which is a counterpart of the Cortlandt series, and borders the plateau on the west. Each marks the locus of a principal fault system which form, respectively, the eastern and western limit of the plateau. By contrast faulting is wanting or inconspicuous in all the central portion of the province.

AMHERST COLLEGE

# SCIENTIFIC BOOKS

*Oxidations and Reductions in the Animal Body.* By H. D. DAKIN, D.Sc., F.I.C., The Herter Laboratory, New York. Longmans, Green & Co., New York. 1912. Pp. viii + 135. Price \$1.40 net.

For some time in the past, "energy" has been the keyword of the theories of nutrition. The problems presented in relation to the transformation of energy in the body were so conspicuous and the technique of investigation so effectively improved in application to the study of the metabolism of energy, that other aspects of the subject were neglected. This trend of the science is reflected in the popular literature of the present time when expressions like "calories" and "fuel value" are employed with the skill of the conjurer to impress the uninitiated. The mere comparison of the intake and the output of the organism and the broad statement that metabolism is essentially a process of oxidation change has, however, long since failed to satisfy the more critical inquirer; and accordingly the questions of what is now termed intermediary metabolism, concerned with the destiny of the individual nutrients or corresponding tissue components, are forging to the front. The newer knowledge of the chemistry of the digestive processes has made great strides in a decade or two. Yet how little we know of the various steps beyond the barrier of the intestinal wall.

It is of certain of these intricate processes considered primarily as chemical reactions that the present monograph aims to give an account. The animus of the attempt at what is essentially a novelty in the literature of physiology may be elicited from a few quotations. Dakin writes:

The statements that fats and sugars are oxidized in the body to carbon dioxide and water, while proteins yield urea in addition, are no longer considered all-sufficient explanations of the chemical rôle of these substances in the animal economy. The study of chemical structure is rapidly changing the whole aspect of biological science, and we may confidently look forward to the time when the orderly succession of chemical reactions consti-

tuting the activities of the living cell will be resolved into their individual phases. . . . It is relatively easy to obtain a balance sheet representing the intake and output of substances in the animal body, but what is fundamentally necessary for the proper appreciation of this balance sheet is a knowledge of the various chemical transactions which (to continue the simile) should be comprised in a trading account. For it is by the proper adjustment and regulation of these transactions that the energy represented by food and tissue substance are economically utilized according to the varying needs of the body. The rapidly developing appreciation of the fact that different proteins, fats and sugars are not physiologically equivalent but that certain definite chemical groups subserve special functions in the animal organism emphasizes the necessity of the study of intermediary metabolism. . . . A true knowledge of metabolic processes can only be obtained by the tedious unravelling of the complex system of biochemical changes into individual chemical reactions. At the present time only a few of these simple reactions have been recognized and studied, but even now it requires little imagination to realize that in the future it will be possible to construct an accurately itemized account of the animal body's chemical transactions, both anabolic and catabolic. The value of such knowledge for the advancement of biology and medicine is sufficiently obvious.

Dakin's book emphasizes the fact that many of the striking biochemical reactions can already be imitated to-day more or less successfully by experiments *in vitro*. This is, of course, a helpful assurance, serving to divert attention from vague speculation regarding subtle vital forces. It has been a popular practise to appeal to hypothetical enzymes to explain some of the obscure chemical transformations in the organism. Thus we have been wandering through the mazes of the oxidases, oxygenases, peroxidases, reductases, catalases and other products of perplexing nomenclature in the hope of escaping the uncertainties of intermediary metabolism. Much of the obscurity is at length dispelled by a vigorous presentation in which questions of chemical structure are paramount and details of biological processes are exemplified in actual experiment or by clear analogy.

In connection with the oxidative capacity of the body Dakin points out the accumulating evidence in favor of the hypothesis of superoxide formation in living cells. With regard to the possibility of biochemical reductions reference is made to the interesting Cannizzaro reaction whereby the reduction of one molecule of substance takes place with the simultaneous oxidation of a second molecule, according to the scheme:

A brief chapter on the methods of investigation formulates the attitude of mind with which the student of intermediary metabolism approaches his problems. It is a decidedly exceptional outline of the viewpoints which may guide the worker in this field in the direction of successful experimentation.

Pointing out that it is only since the publication of Knoop's important studies in 1904 that any material progress has been made in the experimental investigation of fatty acid katabolism, Dakin subjects Knoop's theory of  $\beta$ -oxidation to a critical analysis. He shows that chemical analogies for this are found in the behavior of fatty acids towards hydrogen peroxide, so that by the choice of a suitable oxidizing agent the occurrence of  $\beta$ -oxidation can readily be demonstrated *in vitro*. Physiological experiments continue to furnish striking confirmation of the theory. The relative importance of the  $\beta$ -hydroxy- and  $\beta$ -ketonic acids in the mechanism of the reaction are discussed with abundant reference to the growing illustrative literature to which the author of the monograph has furnished prominent experimental contributions. Other types of reaction than that of  $\beta$ -oxidation have not yet been observed, and it is not likely that  $\alpha$ -oxidation of normal saturated fatty acids takes place in the animal body.

In turn the behavior of the unsaturated acids, the oxidation of acids with branched chains, the dibasic acids, aromatic compounds, amino-, hydroxy- and ketonic acids are reviewed. The intimate biochemical relation

of the latter groups, illustrated by the scheme,

furnishes a text for the discussion of some of the manifold metabolic performances that have only lately found a place in physiological speculations. The oxidation and reduction of amino-acids by microorganisms, with reference to the splendid newer work of F. Ehrlich and of Neuberg in this field, is presented in novel, though brief form. In his treatment of the behavior of the carbohydrates Dakin champions the view that lactic acid must be regarded as one of the most important substances concerned with their intermediate metabolism. There are further chapters on the purines, hydrocarbons, phenols, etc.; and in conformity with the plan of the series of monographs on biochemistry to which this book belongs there is a well-arranged bibliography appended.

The frankness with which open questions are presented, as illustrated in the debated respective rôles of  $\beta$ -ketonic and  $\beta$ -hydroxy acids, is wholesome and marks the unbiased attitude of the book's author, even where his own researches are involved. The reader is impressed with the great advances which have lately been made in the new field covered by this monograph; and whether his interests are primarily those of the physiologist or the chemist, he will be stimulated by the wealth of suggestions—all presented there in a readable form.

*The North American Dragon Flies of the Genus Aeshna.* By E. M. WALKER. University of Toronto Studies. 1912.

It occasionally happens that some familiar group of animals is investigated by one who is sufficiently skilled and independent to detect characters which have escaped all previous observers. I recall the time, now a quarter of a century ago, when certain common land mol-

luses were added to the British list. One of these was almost literally in every one's garden, but until its distinctive characters were pointed out, nobody could see it. To-day the merest beginner can recognize it at once. We are forced to conclude that even excellent manuals are not without their disadvantages, when they are blindly followed by naturalists, who will not even look for things unmentioned by them. The same sort of thing has been very evident in botany, and we have in Mr. Walker's work a remarkable exposure of blindness in the field of entomology. Mr. Walker, during the summer of 1906, was at Lake Simcoe, Ontario, where he interested himself in the common large dragon flies of the genus *Aeshna*. Most people would have viewed them with languid interest as being among the "familiar objects of the country side," completely exploited by entomologists long ago. Not so Mr. Walker, who with critical eye presently discerned that there were more species than the books called for. His curiosity thus stimulated, he pursued the subject further, and was eventually able to establish the existence of sixteen perfectly valid species in temperate North America, five of them described as new by himself. While doing this he has monographed the genus as represented in this country, and now publishes a most exhaustive treatment, discussing the biology, early stages, geographical distribution and other matters. The work is also fully illustrated, with 28 plates and some good text figures. Only one thing seems lacking: I find no mention of Scudder's *Aeshna solida*, which is represented by such beautifully preserved wings in the Miocene shales at Florissant.

The interesting fact is brought out that in addition to "structural" characters, each species has its own color-pattern, which may at once be recognized when known. It is also found that the immature forms, the nymphs, have characters of their own, which are duly set forth in a key. It is thought probable or possible that the genus *Aeshna* is of polyphyletic origin, the *californica* group especially having perhaps a different origin from the

rest. In *Entomological News*, 1908, p. 458, I gave reasons for thinking that *A. californica* deserved subgeneric rank; Mr. Walker's results appear to support this idea, and even suggest the question whether it should not be generically separated, taking with it several related forms.

Certainly Mr. Walker's book should be in every biological laboratory, both as an example of good taxonomy and as a useful work of reference, *Aeshna* being common nearly everywhere.

#### A PRELIMINARY NOTE ON THE COAGULATION OF PROTEINS BY ULTRAVIOLET LIGHT

IN order to gain some insight into the action of ultraviolet light on living cells it became necessary to study its effect on certain constituents of protoplasm. Attention was first given to proteins and a series of experiments were made with egg-white, egg albumin and ox-serum.

1. *Experiments with Egg-white*.—Fresh egg-white was cut up with scissors and placed in a quartz tube, at room temperature, 10 cm. from a quartz mercury-vapor lamp. The tube was completely filled and stoppered. After 1 or 2 hours a feathery coagulum began to form in the tube upon the wall nearest the lamp. This coagulum increased in amount, and after 35 hours the tube was quite full of a flocculent coagulum. There was a peculiar strong odor.

Fresh egg-white was diluted with an equal amount of distilled water. The solution became opalescent from the precipitated globulin. The tube was exposed at room temperature in the same manner as the tube containing the undiluted egg-white. There was a similar coagulation, but it was more abundant. There was also the same peculiar odor. In this case the coagulum slowly settled as it formed. The solution, therefore, was clearer, and there may have been a better penetration of the light. In another experiment the precipitated globulin was filtered out before exposure. Fifteen hours after filtering, the so-

lution was still clear. On exposure to the light a fine sediment was formed which slowly settled to the bottom of the tube. The characteristic odor was present.

In all the experiments described above control preparations in glass tubes, exposed in the same manner, and at the same temperature, gave little or no coagulum, and none of the characteristic odor. The coagulum formed in the quartz tubes, whether they were open or closed. It formed equally well in tubes which had been connected with the air-pump and pumped out so as to remove the dissolved air. No bubbles of gas were formed during the exposure, nor could gases be detected in the solution by pumping with the air pump after the exposure.

2. *Experiments with Crystallized Egg-albumin*.—Crystallized egg-albumin was prepared by the method described by Hopkins and Pinkus. The egg albumin was recrystallized seven times. The ammonium sulfate which came down in the last crystallization was not dialyzed out. Solutions were prepared containing 1, 2, 5, 10 and 20-per-cent. of the albumin. All were exposed in quartz tubes at room temperature. The 5-per-cent. solution gave the most coagulum and in subsequent experiments with crystallized albumin 5 per cent. solutions were used. Coagulation was much more rapid in the crystallized albumin plus the ammonium sulfate, than in the fresh egg-white.

3. *Experiments with Crystallized Egg-albumin Dialyzed Against Tap Water*.—Albumin freed from ammonium sulfate by dialyzing against tap water coagulates very readily when exposed to the light at room temperature. It may be sensitive to longer wavelengths than the fresh egg-white, since considerable coagulum forms in the glass tubes. A quartz and a glass tube were exposed at room temperature for 15 hours. The quartz tube became opalescent and then opaque with a finely divided coagulum which did not settle, but which could be thrown down with a centrifuge. A feathery coagulum formed in the glass tube on the side nearest the lamp. This increased in amount, until the tube was filled

with a feathery coagulum. When the tube was moved, the coagulum separated from wall of the tube and settled to the bottom, leaving the solution in the tube perfectly clear. Further exposure of 20 hours produced only one or two scarcely visible masses of coagulum in the clear solution above the coagulum at the bottom of the tube. The solution contained, however, an abundance of albumin which could be coagulated by heat.

4. *Experiments with Ox-serum*.—The serum was prepared by allowing a clot to form and then decanting off the clear liquid. A portion of this was placed in a quartz test tube and exposed to the light at room temperature. As in the other cases a coagulum formed in the quartz tube while none formed in the glass tube which was exposed at the same time.

The coagulum produced by the light in egg-white and egg-albumin is insoluble in alcohol, hot or cold water and dilute acids. It is soluble in dilute alkalis. In these respects it agrees with the ordinary coagulum which is produced by heat without exposure to ultraviolet light.

LABORATORY OF PLANT PHYSIOLOGY,  
HARVARD UNIVERSITY

#### ASTRONOMICAL AND ASTROPHYSICAL SOCIETY OF AMERICA

The fourteenth meeting of this society was held at the Allegheny Observatory and the Schenley Hotel, Pittsburgh, from Tuesday to Friday, August 27–31, 1912. Sessions were held at the Observatory on Tuesday and Wednesday, the afternoon of Wednesday being occupied by the exercises of dedication of the new observatory. On Thursday and Friday sessions were held at the Schenley Hotel. An excursion to the Homestead Steel Plant of the Carnegie Steel Company, and a visit to the Carnegie Institute added much to the pleasure of the meeting.

The following members were in attendance: A. T. G. Apple, R. H. Baker, L. A. Bauer, B. Boss, J. A. Brashear, Miss Annie J. Cannon, G. C. Comstock, Z. Daniel, H. S. Davis, A. E. Douglass, W. S. Eichelberger, Philip Fox, Edgar Frisby, Miss Caroline Furness, William Gaertner, Miss A. M. Harwood, F. C. Jordan, T. A. Lawes, F. B. Littell, R. J. McDiarmid, J. B. McDowell, D. B.

Marsh, J. A. Miller, O. L. Petittidier, E. C. Pickering, J. S. Plaskett, A. W. Quimby, H. Raymond, E. D. Roe, Jr., H. B. Rumrill, F. Schlesinger, W. L. Scaife, H. Shapley, A. N. Skinner, F. Slocum, Elliott Smith, C. E. St. John, DeLisle Stewart, R. M. Stewart, Miss Helen M. Swartz, S. D. Thaw, Miss Stella May Udick, C. E. VanOrstrand, Miss Sarah F. Whiting.

Visiting astronomers: Louise S. Smith, A. van Maanen.

The following new members were elected: Miss Stella May Udick, Messrs. Harry Raymond, James Hartness, Arthur Newton, Henry G. Gale, David Rines, E. S. Haynes, William L. Scaife, James B. McDowell.

The constitution of the society was amended to provide for the election of honorary members. In accordance with the provisions of the amendment, nominations were received. Sir David Gill was unanimously elected the first honorary member of the society.

The council voted to hold no meeting in the summer of 1913, because of the probable absence of a number of the members in attendance at the Solar Union meeting at Bonn. The next meeting will be in Cleveland during the holidays, 1912, in connection with the American Association for the Advancement of Science. The council voted to hold the 1914 summer meeting at Northwestern University and the 1915 meeting in San Francisco and at the Lick Observatory.

Officers were elected:

*President*—E. C. Pickering.

*First Vice-president*—G. C. Comstock.

*Second Vice-president*—Frank Schlesinger.

*Secretary*—Philip Fox.

*Treasurer*—Miss Annie J. Cannon.

*Councillors 1912–1914*—W. W. Campbell, E. B. Frost.

The councillors who continue to serve are:

*Councillors 1911–1913*—W. S. Eichelberger, J. S. Plaskett.

Abstracts of the committee reports and forty-six papers which were read follow:

*Irregularities in Atmospheric Refraction*: FRANK SCHLESINGER.

This investigation was suggested by the recent work of Nuss and Fric at Prague, who found evidence of irregularities in refraction in a period that is roughly one minute, and having considerable amplitude. At the present author's request Professor Slocum, of the Yerkes Observatory, kindly secured with the 40-inch refractor a number

of plates showing trails of the Pleiades. These plates were exposed on several different nights. Proper precautions were taken to leave the telescope as undisturbed as possible. The trails were measured at the Allegheny Observatory by setting the micrometer wire on the mean position of successive portions of the trail, each corresponding to an interval of about three seconds of time. It was found that on each evening the trails conclusively show the presence of irregular refractions, portions of the trails remaining on one side (of the mean position for that plate) sometimes nearly a minute. On two of the plates simultaneous trails of Alcyone and Merope were measured and these show a remarkable parallelism. The result of this experiment tends strongly to confirm the deductions of Nuss and Frie.

*The Orbit of E Canis Majoris:* FRANK C. JORDAN.

This star, one of the few Algal variables with an advanced type spectrum, *F*, was discovered to be a light variable, by Sawyer in 1887, and to have variable radial velocity, by Frost in 1905. Forty-nine plates have been obtained at Allegheny in five seasons of observation. The light period has been very accurately determined and is taken as the definitive orbital period.

The elements are as follows:  $P=1.13595$  days;  $e=0.138$ ;  $\omega=195^\circ.86$ ;  $K=28.64$  km.;  $\gamma=-43.45$  km.;  $T=1908$ , Jan. 25.296, Light Minimum;  $a \sin i=453,500$  km.;  $m^2/(m+m')^2=0.00288$  ☉.

Accurate photometric observations combined with the orbital elements, and the fact that the spectrum is much like that of our sun, will give an independent means of finding the star's parallax.

*New Eclipsing Variable Stars:* JOEL STEBBINS.

It is probable that a considerable number of the short-period spectroscopic binaries are eclipsing variable stars, and the writer reports progress on tests of these systems with the selenium photometer. It seems practically certain that  $\alpha$  Virginis and  $\alpha$  Coronæ Borealis are such variables, and  $\beta$  Scorpii is suspected. The first, Spica, has a period of 4.014 days, and shows two minima, a primary of something greater than 0.10 mag., and a secondary of about 0.08 mag. The main eclipse of  $\alpha$  Coronæ was observed only once, but it was a decrease of at least 0.12 mag., and came at the predicted time. This star is a member of the extended Ursa Major group, and has a period of 17.36 days. The suspicions of the variation of  $\beta$  Scorpii seem well founded, but need confirmation.

The results emphasize the urgent need of further tests on similar stars.

*The Scale of the Durchmusterung:* E. C. PICKERING.

The number of stars in the Bonn Durchmusterung is about 460,000; in the Cordoba, 490,000; in the Cape, 450,000; total, 1,400,000, or, omitting duplicates, 1,100,000 stars. In the *Harvard Annals*, 23, of the deviations, from the photometric scales, of the magnitudes 9.0 and brighter are discussed. Volumes 70 and 74 permit a similar study of the fainter stars and of those in the Cordoba Durchmusterung whose average brightness differs as much as a magnitude in different hours, the brightness increasing as the number of stars per degree increases. The photometric magnitude of Bonn 9.5 is 10.5; of Cordoba 10 it is 12.0 in zones  $-22^\circ$  to  $-42^\circ$ , and 11.7 in zones  $-43^\circ$  to  $-52^\circ$ . Stars of a given Durchmusterung magnitude are half a magnitude brighter in zones  $-43^\circ$  to  $-52^\circ$  than those in the zones  $-22^\circ$  to  $-42^\circ$ .

The deviations of the Cape Durchmusterung magnitudes from the photometric magnitudes are reduced one half by grouping stars on the same plate and applying a correction for the class of spectrum. The average deviation in a provisional reduction of 12 plates is only  $\pm 0.2$  mag.

*The Progress of the Revised Draper Catalogue:* ANNIE J. CANNON.

The purpose of this catalogue is to give the class of spectrum of all stars down to about the eighth magnitude, distributed over the entire sky. Photographs having exposures of sixty minutes have been made at Cambridge and Arequipa with a prism of small angle placed before the objective of 8-inch doublets, and all stars will be classified which are bright enough to be seen clearly and have not already been published in *H. A.*, 28, and *H. A.*, 56, 4 and 5. Besides the classification the catalogue will give the photographic magnitude, the identification in some position catalogue, and the place for 1900. The catalogue was started in October, 1911. With an hour's observation each day, about 5,000 spectra can be classified in a month. This rate has been maintained since February, 1912, so that at the beginning of August, 45,000 stars have been classified. Charts were exhibited showing that about one third of the sky has been covered.

*A Design for a New Form of Spectrograph Collimator:* PHILIP FOX.

This form was proposed for use with the small

quartz spectrograph of the Yerkes Observatory. As the spectrograph was to be used with the 2-foot reflector, of which the angular aperture is  $f/4$ , the collimator should also have such ratio. The form proposed is in all essentials a small reflector of the cassegrain form. The light coming through the slit falls on the perforated concave mirror, which throws the light upon a small perforated convex mirror, mounted just back of the slit. This second mirror is of such curvature that it throws a parallel beam through the perforation of the first mirror upon the prism. The ratio of perforation to aperture in both cases is equal to the ratio of aperture of the objective of the telescope to the diagonal mirror, and the aperture of the convex mirror is equal to the perforation of the concave, so there is no loss of light. The perforation of the convex mirror centered behind the slit is of sufficient size to permit the use of a slit one eighth of an inch long.

*Systematic Motions of the Stars:* BENJAMIN BOSS.

Diagrams representing the distribution of stars of the different spectral types and down to the 6.5 magnitude were exhibited. The striking preference of the *B* type stars for the plane of the galaxy, the similar, though somewhat less pronounced, preference of the *A* type for the same plane, and the more random distribution of the more advanced types was clearly shown. We must either conclude that eventually a state of approximately random motion must prevail, or that the later type stars originated uniformly over the entire sky, rather than selecting the plane of the galaxy. The facts revealed by the study of the motions of the stars indicate that the first view is the correct one (*A. J.*, 635-636). The early type stars show a decided crowding toward certain portions of the galaxy, toward the vertices of preferential motion, as discovered by Kapteyn, and toward the apex and antapex of a group of stars called Group IV., or the antapex group, discovered by the writer (*A. J.*, 635). That the motion of this group is in the direction of the antapex of solar motion, and that there seems to be a tendency of motion in the opposite direction, may indicate the existence of a solar group. The analysis of the motions within these groups is now in process of development by the writer.

*Observations of Variable Stars at the Vassar College Observatory:* CAROLINE E. FURNESS.

Observations of variable stars were begun at this observatory in 1901. The telescopes in use had apertures of twelve, five and three inches.

A photographic wedge photometer which could be attached to the twelve-inch was in use for part of the time, but for the most part the comparisons were made by the Argelander method. The observing list included chiefly long-period variables which were selected so that they might pass through a maximum or minimum during the time of observation. The predictions were usually taken from Hartwig's ephemeris. The standard of magnitude was the Harvard photometry, other sources being reduced to this scale.

The resulting observations, about five thousand in number, with a full discussion of the curves and periods of the stars so far as they may be determined, are to be published as soon as their revision is complete.<sup>1</sup>

*On the Cause of the Earth's Magnetic Field:*

L. A. BAUER.

The communication is confined to a consideration of the portion of the field which is symmetrical about both the axis of rotation and the equator. If the intensity of the magnetization be computed for each parallel of latitude over the region best covered by magnetic observations, 60° N. to 60° S., on the basis that the average values of the observed magnetic components along a parallel correspond to those of a uniform magnetization parallel to the axis of rotation, then a systematic and regular increase in the intensity is observed in both hemispheres with approach to the equator. This may be stated mathematically thus: If  $X$ , be the magnetic component along a true meridian, positive toward the north, and  $Z$  be the vertical component, positive downward, then for the field, symmetrical as stated, the components, for any co-latitude  $u$ , will be

$$X = f_x(u) \sin u \quad \text{and} \quad Z = f_z(u) \cos u.$$

These "characteristic functions" show an increase of 13 to 17 per cent. from the parallel of 60° to the equator.

None of the theories thus far advanced to account for the origin of the earth's magnetic field gives the law of the observed increase in the characteristic functions. With but few exceptions, the attempts have been restricted to ascertaining a cause for a uniform magnetization. Since this course has not led to generally accepted results, it was decided to begin with the geographical variations, hoping that, if their cause be determined, valuable clues might be found as to the origin of the primary field. Thus a closed physical expres-

<sup>1</sup> See *Popular Astronomy*, 20, 645, 1912.

sion was found, consisting of the zonal harmonics of the first and third order, which represents the facts to within one per cent.

Supposing the bound electrical charges in each atom of the earth to be separated by some cause into positive and negative atomic charges an infinitesimal distance apart, such that the total charge throughout the earth of each kind of electricity be equal and the volume density of each charge vary from parallel to parallel as  $\sin^2 u$ ; then, by reason of the earth's rotation, a magnetic field results whose potential is the expression mentioned in the preceding paragraph. The first term corresponds to a uniform magnetization of the earth parallel to its axis of rotation having about one tenth of the strength of the total portion assignable to a uniform field; the second term, consisting of the third order harmonic, reproduces satisfactorily the observed increase in the characteristic functions. If it be assumed that the separating agency is the component of the earth's centrifugal force acting in the direction of the radius away from the center, a distribution of the two opposite electricities throughout the earth would apparently result, following, as a first approximation, the same law of density, supposed in deriving the expression, the zonal harmonics. Before a final statement, however, can be made as to the precise cause, a more complete examination will have to be made and full consideration be given to all the various effects involved.

*Radial Motion in Sun-spots:* C. E. ST. JOHN.

The results obtained to date indicate the following mean conditions:

Element	Line	Intensity	Direction	Vel. in Km. per Sec.
Ca	H, K		Inward	2.5
H	H $\alpha$		Inward	1.4
Na	D		Inward	0.2
Mg	b		Inward	0.3
Al	$\lambda$ 3961	20	Inward	0.1
Fe	Mean of several near $\lambda$ 5200	6	Outward	0.40
Fe		5	Outward	0.43
Fe		4	Outward	0.52
Fe		3	Outward	0.61
Fe		2	Outward	0.66
Fe		1	Outward	0.75
Fe		0	Outward	0.84

Results similar to those of iron appear for other metallic vapors producing lines of moderate intensities, though the velocities from lines of equal intensities for different elements are not equal.

This offers a means of determining the relative levels at which lines of different intensities have their origin, in terms of some standard such as iron.

Three regions are indicated in the solar atmosphere surrounding spots with the following characteristics at the different levels: (1) The upper chromosphere, motion inward, shown by the H and K lines of calcium and H $\alpha$  of hydrogen; (2) an intermediate region shown by the D lines of sodium, b lines of magnesium, and the strong aluminum and iron lines, motion inward generally prevailing; (3) a lower region of outward motion, velocity increasing with lower levels, on the assumption that when considered by and large the weaker lines are associated with the lower levels.

*Pressure in the Solar Atmosphere:* C. E. ST. JOHN.

In the new spectrograph of the 150-foot tower telescope the sources of error associated with the instability of the apparatus, the illumination of the grating and the centering of the solar image, have been overcome, the first, by the massive construction of the spectrograph, the head of which weighs about 4,500 lbs.; the second, by the larger diameter, 15 inches, of the cone of sunlight incident upon the grating which the long focus, 75 feet, of the spectrograph permits when the 12-inch objective of 60-foot focus is used to form the solar image on the slit; the third, by fixing the slit rigorously on the axis of the centering circles. The error introduced from non-centering of the image may be large; with the image now used (diameter 162 mm.) the solar lines would be shifted 0.001 Å. by solar rotation when the slit is 2 mm. from the center of the image and on small images the error might be much greater.

With this equipment an investigation involving a comparison of the arc and solar spectra of iron is being carried out. The preliminary results show that the solar lines of iron classified in accordance with their displacement in solar spectrum fall into the classes suggested by Gale and Adams in their study of pressure shift under laboratory conditions and indicate pressures in the solar atmosphere varying from 0.7 to 6.5 terrestrial atmospheres for the different groups.

*On the Diurnal Variations of Atmospheric Pressure:* W. J. HUMPHREYS.

It has been known for nearly two and a half centuries that there are more or less regular daily variations in the height of the barometer, culminating in two maxima and two minima during the course of the 24 hours; the maxima occurring

at 10 o'clock, roughly, forenoon and evening, the minima at 4 o'clock, roughly, afternoon and morning.

All that is needed, apparently, to give the semi-diurnal pressure curve, is a pressure impulse of the same period, 12 hours, as that of the free vibration of the atmosphere as a whole. And this, it seems, is furnished by a forced forenoon barometric maximum, due to the interference of vertical convection with the free flow of the air, followed, six hours later, at the same place by a forced afternoon barometric minimum, caused by expansion and overflow. In other words, taken together the forenoon and afternoon forced disturbances appear to occur with the proper time interval necessary to set up and maintain the 12-hour free vibrations of the atmosphere.

The course of events at each locality, affecting the height of the barometer, appears to be substantially as follows: (1) A forced forenoon compression of the atmosphere followed by its equally forced afternoon expansion; both due to a single heating and the two together forming one complete barometric wave, with a 10-o'clock maximum and a 4-o'clock minimum, in harmony with the free vibration of the entire atmosphere shell. (2) Non-disturbance through the night, or during the period of a single free vibration. (3) Repetition the following day of the forced disturbances in synchronism with, and therefore at such time as to reinforce, the free vibrations. The series of disturbances of course is indefinitely great, alternately forced and alternately free, but the resulting amplitudes of the barometric changes are limited, through friction and through the absence of perfect synchronism, to comparatively small values.

*A Screen for Equalizing Star Magnitudes for Transit Circle Work:* F. B. LITTELL.

The equalizing screen consists of two sets of thin brass slats at right angles to each other, intermeshed to form a rectangular, honeycomb structure. The slats are 1/2 inch wide, 1/120 inch thick and 1/5 inch apart, and make an angle of 45° to the plane of the meridian. The whole is mounted about 3 inches in front of the objective and may be tilted about an axis parallel to the horizon, the operation being effected and the amount read at the eye end. The light which falls on the objective is evenly distributed in nearly rhombic areas. A tilt of 30° gives total extinction. The bright spectral images formed by the bright stars which vary in character with the set-

ting of the screen can be rendered practically invisible in a bright field by preliminarily reducing the light by means of one or both of the two wire mesh screens which have been used on the instrument for several years and which are retained for this purpose.

*24-inch Objective of the Sproul Telescope:* J. A.

MILLER and R. W. MARIOTT.

The 24-inch objective for the Sproul telescope by the John A. Brashear Co. was completed and mounted in the Sproul Observatory of Swarthmore College in December of 1911. This paper discussed the quality of this objective as determined by the Hartmann method. In February of 1912, extra focal exposures on Capella were made through a screen containing 44 circular holes, 33 mm. in diameter, so arranged as to cover 9 zones of the lens. The exposures were made on Cramer Instantaneous Isochromatic plates. A yellow ray filter made by Wallace in accordance with the color curve of the objective was placed in front of the plate and almost in contact with it. Later a set of extra focal exposures were made on Arcturus in the same way. In the meantime, however, a spring holding the lens in its place in the cell was slightly loosened. The exposures on Arcturus were through a screen containing 78 circular holes of 25 mm. diameter, so arranged that it covered 10 zones. The measure demonstrated that qualitatively the two tests showed slight axial stigmatism, at approximately the same points in the lens. Hartmann's characteristic  $T$  for the Arcturus test is 0.270 and for the Capella test, 0.274, showing that the lens is an excellent one.

*The Orbits of 44 Eclipsing Binaries:* HARLOW SHAPLEY.

Using the methods recently developed by Professor Russell, orbits have been computed for all eclipsing variable stars for which there exists reliable photometric data. Included in the material discussed are unpublished observations made by the writer with the Princeton polarizing photometer of the stars *EZ* Draconis, *RX* Draconis, *EE* Draconis, *WZ* Cygni, *AE* Cygni, *ZZ* Cygni, *EW* Capricorni, *RX* Herculis and *EW* Monocerotis. The periods of a few stars have been redetermined. Secondary minima have been found from an analysis of maximum light observations in the cases of *U* Cephei, *E* Canis Majoris, *EZ* Draconis, *ST* Carinae, *SU* Centauri and *SZ* Centauri, and possibly for *S* Cancri,  $\delta$  Librae and *EW* Monocerotis. The investigation of the light curves of

*U* Ophiuchi, *RZ* Centauri and *SZ* Centauri shows that the periods of these variables are double the values heretofore given, for in each case two minima of unequal depth alternate. This is also probably true for *SS* Carinæ and for *RX* Draconis.

For more than 80 per cent. of the orbits studied circular elements represent the observations satisfactorily. In no instance has an orbital eccentricity been found to exceed 0.1. The fainter component is very generally the larger of the pair. In only one case out of nine is the dark companion definitely smaller. Pairs of equally luminous stars are rare; equal radii are more common.

The elongations of the component stars through gravitational interaction has affected the shape of the light curves for one third of the number here considered to a degree sufficient to be taken into account in the discussion of the orbits. The square of the eccentricity of a meridian section of the assumed similar prolate spheroids is greater than 0.30 for  $\beta$  Lyrae, *RS* Sculptoris, *RR* Centauri and *V* Puppis; it is greater than 0.20 and less than 0.30 for *U* Pegasi, *U* Scuti and  $\alpha$  Herculis; and between 0.10 and 0.20 for *U* Ophiuchi, *V* Serpentis, *RZ* Centauri and *SZ* Centauri. These data have enabled the comparison of the *observed* relation between the prolateness and distance of centers with the *theoretical* relation derived by Darwin for equal masses of homogeneous, incompressible fluid. A remarkable agreement is found.

The densities of the pairs were computed in terms of the sun's density, on the assumption of equally massive components. An important relation is found connecting density and spectral type. The average density of nine stars of Classes *B1* to *B8* is 0.16; of 26 stars of Class *A* it is 0.13; but for eight stars of Classes *A5* to *F* the average is 0.55. No star of the first two groups has a density as great as one half that of the sun; and the solar density is not exceeded by any in the third group.

A general investigation has been made in connection with Professor Russell of the theory of darkening at the limb in eclipsing variables and of the relation existing between orbital elements derived on the assumption of uniformly illuminated disks and of disks darkened to zero at the limb. Tables analogous to those used in deriving elements on the former assumption have been constructed.

*On the Graphical Representation of Eclipsing Variables:* HENRY NORRIS RUSSELL.

The computed elements of an eclipsing variable

are admirably adapted for graphical illustration. A diagram of the system as seen from the earth exhibits at a glance all the geometrical elements. By a proper choice of scale, it may be made to show much more. If we assume that each component is equal in mass to the sun, their mean distance (in solar radii) will be  $5.29 P^{2/3}$ , where  $P$  is the period in days. If plotted on this scale, the radius of the orbit will at once indicate the period, and those of the individual stars their probable densities (on the usual assumption of equality of mass). By suitable shadings, the relative surface brightness may also be indicated, and thus practically all the facts for several systems may be displayed on a single sheet.

Such diagrams also give, in all probability, a very good idea of the actual dimensions of the various systems. No stellar system has yet been reliably investigated whose mass is less than one fourth that of the sun; and masses exceeding sixteen times the sun's are very rare. It follows that the actual dimensions of a given system, compared with the sun, are very unlikely to be more than twice, or less than half, those indicated by diagrams prepared as above. Since most eclipsing variables are too faint for direct spectrographic investigation, this is probably the best way at present available of getting an idea of their real size.

*Relation Between Spectrum and Color-index of 500 Stars:* J. A. PARKHURST.

The revised data from the writer's forthcoming catalogue of magnitudes and spectra of northern stars<sup>2</sup> furnishes material for a curve showing the relation between spectrum and color-index. The range in magnitude of the stars used is between 4 and 9, the greater number lying between 6 and 8.5. The average magnitude is 7.3 visual, corresponding to 7.7 photographic since the color-index of the average star is 0.4. The Harvard classification is used.

Plating the color-index as abscissæ and the spectral class as ordinates, a straight line is found to fit the points better than any simple curve. The lantern slide accompanying the paper shows a comparison between this "curve" and those published by King in *Harvard Annals*, 59, 180, and Schwarzschild in his Göttingen *Aktinometrie*, B, 19. King's stars are mostly brighter than magnitude 4.5, while Schwarzschild's are about the same brightness as those measured by the writer. The present work differs from the other

<sup>2</sup> *Ap. J.*, 36, 169, 1912.

two, in that all elements used were determined by the same person and the same instrument.

*The Attraction of Sun-spots for Prominences:*

FREDERICK SLOCUM.

In the autumn of 1910 a large group of sun-spots passed several times across the face of the sun. On its first passage, from August 2 to August 15, it was given the Greenwich number 6,874.

Active prominences were observed in the immediate vicinity of the spot group from August 2 to November 5, but the best displays occurred on the west limb on October 8, extending from Lat.  $+6^\circ$  to  $-37^\circ$ , and on the east limb on October 22, extending from Lat.  $+12^\circ$  to  $-36^\circ$ . Slides of calcium spectroheliograms of the spot, the surrounding flocculi and the attendant prominences were shown.

The prominences were pouring from both sides apparently right down into the spot. Points that can be identified on two or more plates give velocities along the apparent trajectory up to 110 km. per second, and show a marked acceleration towards the spot. The conclusion is that some sun-spots exert an attraction for the material of which prominences are composed.

No.	Star	$\pi$	P. E.	Remarks
1	$\phi$ Androm.	$+0.014$	$\pm 0.017$	Visual binary.
2	48 Cassiop.	$-0.001$	$\pm 0.015$	Visual binary.
3	20 Persei	$-0.008$	$\pm 0.006$	Visual binary.
4	9 Camelop.	$+0.030$	$\pm 0.005$	Spectroscopic binary.
5	$\mu$ Orionis	$+0.036$	$\pm 0.007$	Spectroscopic binary.
6	Groningen VII. 20	$+0.129$	$\pm 0.012$	Faint star with large proper motion.
7	BD 18°, 3424	$+0.004$	$\pm 0.014$	Faint star with large proper motion.
8	17 Lyre C	$+0.128$	$\pm 0.008$	Faint star with large proper motion.
9	P Cygni	$-0.014$	$\pm 0.008$	Nova?

11	Nova Lacertae	$+0.011$	$\pm 0.013$	Nova.

*Stellar Parallaxes from Plates made with the Forty-inch Refractor of the Yerkes Observatory:* F. SLOCUM and S. A. MITCHELL.

The present parallax program contains about 150 fields, including (a) stars with large proper motion, (b) stars with large radial velocity, (c)

binaries, visual and spectroscopic, (d) selected stars of the different spectral types, (e) novæ, and stars in any way peculiar, (f) the Kapteyn zone  $+45^\circ$ . The following parallaxes have recently been determined:

The average number of plates used for each of the above determinations is eleven, the average number of comparison stars, five, and the average magnitude of the comparison stars, 9.6. Numbers 3, 4, 5, 9 and 10 were measured and reduced by Professor S. A. Mitchell, of Columbia University, and numbers 1, 2, 6, 8, 11 by Professor Slocum, and number 7 by Miss M. M. Hopkins, of Smith College.

*The Spectrum of Nova Geminorum No. 2 on March 13, 1912:* R. H. CURTIS.

The Detroit Observatory slit spectrograms of Nova Geminorum II. secured on March 13, 1912, show characteristics which have important bearing on the nature of the spectral changes of a nova as it approaches its maximum radiance. The nova's spectrum on this date strongly resembles that of March 15, when the nova maximum type was generally recognized, the peculiarities of the light on the earlier date being strongly accentuated two days later. The conclusion is suggested that the peculiarities of the nova type appeared in the spectrum of this star earlier than has been supposed.

*The Plane Grating Spectrograph for Stellar Work:* J. S. PLASKETT.

This paper gives a short account of some preliminary tests on the use of a plane grating as the dispersion piece of a stellar spectrograph. The grating with ruled surface  $2\frac{1}{2}$  by  $3\frac{1}{2}$  inches, 15,000 lines to the inch, was specially ruled to give great concentration and it is estimated that 50 per cent. of the incident light is diffracted into the first order on one side. The spectrograph has been tested only in the Littrow form, with a  $2\frac{1}{2}$ -inch Brashear Triplet of  $37\frac{1}{2}$ -inch focus, giving a linear dispersion of about  $17.5 \text{ \AA. per mm.}$  at  $H_\gamma$ . It gives beautiful definition and a field very nearly flat over the range used from  $\lambda 4800$  to  $\lambda 3500$ . The relative intensity of star spectra obtained with this instrument, and the Ottawa three-prism spectrograph with a camera objective giving the same dispersion at H is as follows: Region  $\lambda 4700$ – $\lambda 4300$ , prismatic about twice as intense as diffraction spectrum. Region  $\lambda 4300$ – $\lambda 4200$ , spectra of nearly equal intensity. Region  $\lambda 4150$ – $\lambda 4100$ , diffraction two to three times as intense

as prismatic spectrum. Region  $\lambda 4100$ - $\lambda 3850$ , diffraction spectrum of nearly uniform intensity and nearly as strong as at  $H_{\gamma}$ . Prismatic spectrum, none. It is evident that with this dispersion the diffraction spectrograph is superior, especially towards the violet and ultraviolet. When it is compared with a single prism spectrograph of lower dispersion the advantage will likely be the other way, but if a spectrum of uniform intensity over a wide range is required, and in the red end, where the prismatic spectrum is unduly compressed, the grating spectrograph will undoubtedly possess many advantages. As soon as possible a more complete test of its performance will be made.

*The Cincinnati Astronomical Society:* DELISLE STEWART.

This paper describes the organization and activities and plans of the society. The suggestion is made that some definite connection between the national and local societies might be worth consideration.

*Radium and the Chromosphere:* S. A. MITCHELL.

This paper has been published in *A. N.*, 4600, so only the conclusions need be given here.

At the 1905 eclipse, while a member of the U. S. Naval Observatory expedition in Spain, the writer photographed the "Flash Spectrum" with such dispersion and definition that it permitted the determination of wave-lengths which are in error but a few hundredths of an Ångström. A comparison with the radium spectrum showed that a majority of the lines due to radium nearly coincide in the chromosphere with lines already satisfactorily identified from other sources. The third strongest line of radium at  $\lambda 4826.10$ , if present in the chromosphere, must be very weak. The comparison between the spectra of radium and of radium emanation and the chromosphere has led me to the conclusion that there are no radium lines in the sun. A similar lack of uranium lines likewise appears.

It will be necessary to obtain photographs of novæ with a much greater dispersion than that used at Bonn before deciding that radium or uranium lines are found in their spectra.

*Absorbing Medium in Space:* EDWARD S. KING.

The results given in *Harvard Annals*, 59, indicated the presence of an absorbing medium in space. The amount found was 0.0377 mag. for the photographic rays, and 0.0184 mag. for the visual rays, while traversing the unit of distance, which is measured by 32.6 light-years.

These figures having been derived from 26 stars, it was thought best to improve the data by applying the method to other stars. Accordingly, a supplementary list of 22 stars was prepared from the *Publications of the Groningen Laboratory*, No. 24, and observed. The procedure was in all respects precisely that followed previously. The resulting values had the same sign, indicating absorption by greater redness, but were somewhat larger than before. By selecting from both lists only those stars having the parallax most accurately determined, the reduction gave values identical with the above results from *Harvard Annals*, 59. Thus, the indications from this work also point to the presence of an absorbing medium in space, or some factor which produces effects similar to absorption by making the more distant stars appear redder.

*Proper Motions of Faint Stars:* GEORGE C. COMSTOCK.

The writer, who has been engaged for some years upon a study of the motions of the faintest stars for whose determination adequate material can be found, presents in this paper results relating to more than 250 stars fainter than the tenth magnitude of the Harvard scale. These motions have been derived from micrometer observations by which the positions of the faint stars are referred to neighboring brighter ones of known proper motion, the time interval covered by the measures being in a few cases as small as a quarter century but more frequently extending to fifty or seventy-five years. The probable error of the motion assigned each star in each coordinate has been determined, and from a comparison of these numbers with similar data given in Boss's Preliminary General Catalogue it appears that the proper motions here considered, tenth to thirteenth stellar magnitude, are at least of equal precision with those given for the fainter stars of the Boss Catalogue, 7.5 to 9.0 magnitude. The proper motions here considered are all referred to the Boss system.

In a certain number of cases the motions here investigated are shown to be orbital, the faint star being physically connected with its brighter companion; but when the angular distance separating the stars exceeds the Struve double-star limit of 32" this connection is found to be very infrequent and in about 80 per cent. of the cases here investigated, *i. e.*, more than 200 stars, the motion of the faint star appears to be uninfluenced by its

brighter companion. Frequency curves showing the distribution of total proper motion and of motion in both right ascension and declination were exhibited and certain suggestions relative to the structure of the stellar system were derived from them; *e. g.*, the mean motion of these stars, about 3".5 per century, is larger than has usually been supposed, indicating a smaller total extent than is commonly attributed to the sidereal universe. A general southerly drift, shown by these stars, suggests that in great part they lie outside a group associated with the sun and comprising a large part of the brighter stars. The precession constant furnished by these faint stars is shown to be in excellent agreement with that found by Boss from the brighter stars, implying that these bright stars possess, as a whole, no motion of rotation about the earth's axis that is not shared by the fainter stars.

A curious empirical relation, long known but little heeded, is confirmed and considerably extended by these results, viz., the product, stellar magnitude multiplied by proper motion, is approximately constant over all magnitudes from the second to the eleventh, inclusive, and unless there are conditions of the problem not now apparent this relation would imply that in the average of a large number of cases a star's distance from the sun is proportional to its numerical magnitude. This suggestion is probably of too revolutionary character to be readily accepted, although it is paralleled by the conclusion reached by Campbell from spectroscopic evidence that the stars of different magnitudes are more thoroughly intermixed in space than has been commonly assumed.

*The Solar Eclipse of April 16, 1912, as Predicted and as Observed:* ARTHUR NEWTON.

The Nautical Almanac Office is preparing for the press the final installment of Professor Simon Newcomb's "Researches on the Motion of the Moon." Corrections therein given have been applied in the American Ephemeris and Nautical Almanac for 1912 to the moon's position in the computation of the two solar eclipses of the present year.

The many observations made on April 17 are entirely confirmatory of the accuracy of these final values by Professor Newcomb. The American Almanac gave a predicted time of occurrence that was within two seconds of the mean observed time. The European almanacs were in error from 15 to 30 seconds. The central line of eclipse was placed about one mile too far to the northwest by

the American Almanac, and much farther in the same direction by the other almanacs, with the exception of the French.

These results indicate that the moon's position as employed in the American Ephemeris for this eclipse required a further correction of  $+1''.0$  to the longitude and of  $-0''.5$  to the latitude. The prediction was further borne out in the phase which was total in Portugal and Spain with a maximum duration of one second, and annular in France with a duration of three or four seconds at Paris. The indicated correction to the adopted semi-diameter of the moon is less than  $0''.2$ .

*A Method of Approximating Rainfall over Long Periods and Some Results of its Application:*  
A. E. DOUGLASS.

It was found by a test extending over 43 years that the radial thickness of the rings of the yellow pine of northern Arizona gives a measure of the rainfall in that vicinity with an average accuracy of over 70 per cent. By applying a simple formula, taking into account the conservation of moisture, the accuracy may be increased to about 75 per cent. By cross identification of rings between all the hundred trees examined, the accuracy of counting rings was greatly increased.

Five trees from the vicinity of Flagstaff were measured to the number of 400 rings, and two of these to 500. It was found that all the trees in that locality gave very similar records. A 21-year variation amounting in all to 20 per cent. of the mean is shown in 400 out of the 500 years recorded. A shorter variation amounting to 16 per cent. of the mean was found to have a period of 11.4 years. Its plot derived from 492 years shows 2 maxima which correspond in time with 2 maxima of rainfall in the 50 years of records on the southern California coast. These in turn match the major and minor maxima in the temperature of that region for the same period. The larger maximum of the latter occurs at the time of the sun-spot minimum as averaged for 125 years.

*The Algol Variable RR Draconis:* F. H. SEARES.

The writer made an attempt to determine the light curve of this star from observations with the  $7\frac{1}{2}$ -inch refractor of the Laws Observatory. On account of its faintness it could not be followed through the minimum. On August 7 the star was followed photographically through an eclipse with the 60-inch reflector of the Mt. Wilson Observatory. Sixty-five exposures, covering an interval of 6 hours, were obtained. The variable is normally of 9.70 mag. There is an interval of

constant minimum brightness, lasting about  $1\frac{1}{2}$  hours, during which the magnitude is 13.50. The duration of eclipse is  $8\frac{1}{2}$  hours. The light change is very rapid, the last magnitude of the descent is accomplished in 20 minutes. For two magnitudes of the descent the visual and photographic curves are in close agreement, but from this point the photographic variation seems more rapid than the visual. For  $\Delta m = 3.25$  mags. visually, the photographic value is 3.50. This greater photographic range is probably real. The observed time of minimum was eleven minutes late of the ephemeris from the elements of the Lays Observatory Bulletin No. 9, indicating a correction to the period, which is slightly less than  $2^d 20^m$ , of less than a second.

*Spectrographic Observations of  $\phi$  Persei:* FRANK C. JORDAN.

This star has been known, since 1889, to have a bright line spectrum. About 400 spectrum plates have been obtained by various observers, and its period determined as 126.5 days. The hydrogen lines are constituted as follows: A broad, weak, underlying absorption, upon which is superposed a broad emission line appearing as two because of a central narrow and strong absorption. The sharpness and strength of the absorption lines varies strikingly in different parts of the orbit, becoming at one phase so weak and diffuse as to be almost immeasurable. Helium lines show only at certain phases. There are visible at least twelve other bright lines which seem to be constituted like the hydrogen lines, and to give the same velocity as these lines.

The velocity curve is peculiar in that at about one third of the period from maximum positive velocity there is a decided hump. The highest velocity is  $+44$  km. It goes down to  $-7$  km. at phase 24 days, up to 0 km. at phase 35 days, then down to a minimum of  $-21$  km. at phase 75 days. In different revolutions of the system the velocity curves do not seem to be the same either in shape or amplitude.

Preliminary measures on the bright hydrogen lines give a velocity curve different from that of the absorption lines, but not such a curve as would be given by a secondary body.

*Spectrographic Observations of Algol:* FRANK SCHLESINGER.

Algol has been upon the observing list for the Mellon spectrograph during the past six years. A total of 336 spectrograms have been secured, and have been measured and reduced by the

author under as uniform conditions as possible. A study of this material yields the following chief results: (1) The long period oscillation in the radial velocities, announced by Belopolsky in 1906, is unmistakably confirmed. This oscillation has a period of 1.874 years and a semi-amplitude of 9.14 km., and is in an orbit whose eccentricity is small. (2) Such an oscillation should be accompanied by a similar oscillation in the times of light minimum, the latter sometimes occurring as much as 5 minutes in advance and sometimes 5 minutes after the predicted epochs. An examination of the rich photometric material on this star obtained in the years from 1852 to 1887 brings out this small term with almost precisely the amplitude computed from the spectrographic measures. (3) The eccentricity of the short-period orbit (2.87 days) comes out small, very probably less than 0.02. This seems to make it necessary to reject Tisserand's explanation for Chandler's long-period term (141 years) in the times at which light minima occur, since this explanation demands an eccentricity in the neighborhood of 0.13. A renewal of photometric observations of Algol is much to be desired, as well as a rediscussion of all the available data of this kind.

*The Orbit of  $\lambda$  Tauri:* FRANK SCHLESINGER.

Eighty-nine spectrograms of this bright Algol variable have been secured with the Mellon spectrograph at the Allegheny Observatory. These yield the following elements of its orbit: period (assumed from photometric data), 3.9529 days; semi-amplitude  $58.1 \text{ km.} \pm 1.08 \text{ km.}$ ; eccentricity,  $0.053 \pm 0.017$ ; longitude of periastron,  $111^\circ.6 \pm 20^\circ.5$ ; time of periastron passage, 0.31 days after light minimum  $\pm 0.23$  days; mean velocity,  $+13.6$  km.

The lines in the spectrum of this star are affected by shadings alternately on their red and violet sides. These can not be due to the presence of the fainter spectrum, since they are too close to the lines of the bright spectrum to permit of this explanation. The spectrograms are all upon plates of fine grain.

*The Magnitude Scale of the Polar Sequence:* F. H. SEARES.

The methods of photographic photometry employed with the 60-inch reflector of the Mt. Wilson Observatory involve the use of a wire gauze screen and diaphragms of various apertures. The most troublesome difficulty has been the determination of the error depending on the distance of the stars from the axis of the instrument which varied

from plate to plate and with direction on the same plate. The erratic variations seem now to be eliminated. At present, the point of greatest interest in photographic photometry relates to the determination of an absolute scale. The first determination of magnitudes has been for stars of the polar sequence. Fifteen plates with the wire gauze screen and diaphragms of 32 and 14 inches, affording 27 separate determinations of the scale, have been used. The exposures range from 1 to 11 minutes, the magnitudes from 8.8 to 17.6, although the limits for reliable results are 10.5 to 15.5. The mean deviations of groups of stars from results obtained at the Harvard Observatory are as follows:

Magnitude	Mt. W.-H.	No. Stars
8.81	+ 0.11	1
10.5 — 11.5	— 0.03	6
11.5 — 12.5	— 0.02	4
12.5 — 13.5	+ 0.03	6
13.5 — 14.5	+ 0.03	5
14.5 — 15.5	— 0.01	5
15.5 — 16.5	— 0.13	4
16.5 — 17.5	— 0.27	7

The zero point of the Mt. Wilson scale is such that the sum of the deviations from the Harvard scale between 10.5 and 15.5 is zero. The cause for the divergence beyond mag. 15.5 is not yet established, but may be settled by comparing the scale here given with that derived from plates of longer exposure.

#### *Variable Asteroids:* S. I. BAILEY.

In connection with the photometric measurements of Eros, made at Arequipa in the years 1902 and 1903, observations of Ceres, Parthenope, Massalia, Kalliope, Urania, Harmonia, Melete, Hecuba, Sirona, Baucis, Celuta, Chryseis, Kallisto, Kleopatra, Germania, Bambergia, Tercidina, Melusina, Ilmator, Aquitania, Aurelia, Eros and Tergeste, were undertaken especially for the detection of new cases of variability in light. The Rumford photometer was used with the 13-inch Boyden telescope. Five cases of variability, in addition to Eros, were detected: Urania (30); indications of variability, no satisfactory period found. Hecuba (108); indications of a small range of variation, having a period which appears to be a sub-multiple of 0<sup>d</sup>.99, perhaps 0<sup>d</sup>.330. Sirona (116); indication of range of half a magnitude with period 0<sup>d</sup>.403. Celuta (186); variation small, if real, period 0<sup>d</sup>.364 satisfies all ob-

servations. Tercidina (345); small variation, satisfied with period 0<sup>d</sup>.366.

The light curves of Eros independently determined by the Rumford photometer and by photographs made with the Bruce telescope agree closely, but those obtained with the photographs have the smaller accidental errors. The photographic method offers many advantages. In order that photographs shall serve for the accurate determination of magnitudes, it is very desirable that the images of the asteroids shall be comparable with those of the stars. This can be accomplished by giving to the plate, while the telescope is moving at sidereal rate, a motion equal to one half the apparent motion of the asteroid.

#### *Results of Latitude Observations at the Flower Observatory from December, 1904, to July, 1911:* C. L. DOOLITTLE.

The series here considered consists of 13,852 determinations of latitude made with the zenith telescope, and 11,591 with the Wharton reflex zenith tube. All of the observations were made by myself and the two series are practically simultaneous. A comparison of the results given by the two instruments furnishes data, to be found nowhere else, so far as I know, for examining the daily fluctuations to be found in all extended series of this character.

For this purpose we have 1,540 comparisons. We find 149 cases where the residuals from both series are at least twice the probable error. Of these, 79 have like signs and 50 unlike. There are 12 cases where both residuals are at least three times the probable error; 10 of these have like signs. In these cases the residuals are four times the probable error and in one case six times the probable error. All of these have like signs.

It is obvious that we have to do with a class of errors other than those due to observations, and that before much greater progress can be hoped for in this direction, means must be found for this elimination.\*

#### *The Constant of Aberration:* C. L. DOOLITTLE.

From the observations carried on at the Sayre and Flower Observatories from December 1, 1889, to June 8, 1911, with the zenith telescope and the reflex zenith tube there have been derived 22 values of this constant. Although these range in value from 20".448 to 20".605, the computed value of the probable error in no case differs very much from 0".01. If we give all equal weight we have

\* See A. J., 641.

for the arithmetical mean of all,  $20''.526 \pm 0''.0057$ . There are, however, very good reasons for assigning higher weights to some of the 22 values than to others. The results have been derived from observations at two different places with practically four different instruments. We find, however, for the weighted means practically the same value as that given above,  $20''.525 \pm 0''.0045$ . The corresponding value of the solar parallax is  $8''.780$ .<sup>4</sup>

*A Test of the 18½-inch Objective of the Dearborn Observatory Telescope:* PHILIP FOX.

It has been interesting to apply Hartmann's test to this objective, the high quality of which is established by the long series of difficult double-stars which have been discovered with its aid by both Burnham and Hough. The perforated screen contained 96 holes, 12 mm. in diameter, arranged on 24 zones. The resulting curve of zonal foci is very smooth. The extreme range in focal length for the different zones is about 2 mm. The mean of the two sets gives for the Hartmann criterion  $T$ , the result  $T = 0.30$ .

*Some Results from the Personal Equation Apparatus of the 9-inch Transit Circle of the U. S. Naval Observatory:* W. S. EICHELBARGER and F. B. LITTELL.

With a personal equation apparatus the following results were obtained for the three observers,  $L$ ,  $M$ ,  $P$ , positive corrections indicating that the observer anticipates.

CHRONOGRAPHIC OBSERVATIONS

$\delta$	Sec $\delta$	$L$		$M$		$P$	
		RL	LR	RL	LR	RL	LR
		s	s	s	s	s	s
0°	1.0	-0.132	.....	-0.038	.....	-0.060	.....
39	1.3	-0.131	-0.135	-0.028	-0.038	-0.077	-0.100
62	2.1	-0.130	-0.167	-0.018	-0.045	-0.057	-0.112
82	7.4	-0.120	-0.188	-0.053	-0.058	-0.129	-0.153
85.1	11.7	-0.115	-0.203	-0.021	-0.037	-0.062	-0.112

EYE AND EAR OBSERVATIONS

85.1	11.7	+0.29	+0.23	+0.02	+0.05	+0.18	+0.23
87.7	24.9	+0.39	+0.29	-0.04	+0.18	+0.25	+0.27
88.9	52.1	+0.78	+0.64	+0.15	+0.26	+0.55	+0.68

Assuming that the personal equation can be represented by  $p + m \sec \delta \pm n \sec \delta$ , the coefficients were computed and corrections applied, thus reducing the errors to a very small quantity, generally less than  $0''.01$  for chronographic, and less than  $0''.05$  for eye and ear observations.

<sup>4</sup>See *A. J.*, 639, and Pub. Flower Observatory, Vol. III., 2.

Comparisons were made to test the reliability of these results, with satisfactory consequence.

*A High-level Measurement of Solar Radiation:* FRANK W. VERY.

Applying the methods elaborated in a previous paper, "The Violle Actinometer as an Instrument of Precision," to the reduction of an observation by M. Violle, who obtained from a sounding-balloon record at an altitude of 13,700 m. an excess of  $53^\circ$  in sunshine above an air temperature of  $65^\circ$  below zero Centigrade, the author obtained for the observed solar radiation-equivalent at 13,700 m., 2.86 gram cal./sq. cm. min. Making allowance for the absorbent atmosphere, deriving the value from the consideration of observations at sea-level, Keeler's and Nanry's on Mt. Whitney, Violle's on Mt. Blanc, the value of the solar constant obtained is 3.5 gram cal./sq. cm. min.

*A Criterion of Accuracy in Measurements of Atmospheric Transmission of Solar Radiation:* F. W. VERY.

The coefficient of atmospheric transmission of solar radiation on a given day is variable because of the variation of atmospheric extinction with zenith distance, and because this absorbent quality changes in the middle of the day, especially if much moisture is present. Thus in Bouguer's formula,

$$R = Ap^x,$$

there are two variables  $p$  and  $x$ , and the equation is soluble only by approximation.

To accomplish this approximation, M. Crova has proposed that the curve of radiation shall be considered as the envelope of a series of logarithmic arcs. By constructing successive sub-tangents to this envelope at points having values of  $x$  for abscissæ, coefficients of transmission of the sifted rays, at stages corresponding to determined values of  $x$ , can be found by the equation

$$T = e^{-\frac{1}{m(1+\epsilon)}},$$

where

$$m = \log \left( \frac{1 + \epsilon_1}{1 + \epsilon_2} \right) \div \log \left( \frac{R_2}{R_1} \right).$$

This procedure usually gives a series of varying values of  $m$ , so that a solution of the problem is no nearer, unless some occasion can be found when  $m$  does not vary appreciably. Such an extraordinary occasion is on record in the observation by Savélief at Kief, Russia, December 28,

<sup>5</sup>*Pub. A. A. S. A.*, 2, 90.

1890, which may be used as a test by which less perfect measurements may be judged. By theory, we have the criterion that  $1/m$  must always be a fraction. Rejecting all observations which do not conform to this criterion, also midday observations which are affected by the usual midday depression, the author compares the mean of the two series of observations by Kimball with Savélie's measures. The mean values are:

$$\epsilon = 7, \text{ Savélie } 1/m = 0.647,$$

$$\text{Kimball } 1/m = 0.786;$$

$$A = (1 + 7)^{0.647} \times 0.94 = 3.606 \text{ (Savélie)};$$

$$A = (1 + 7)^{0.787} \times 0.72 = 3.698 \text{ (Kimball)}.$$

Application of the criterion brings these otherwise discordant observations into agreement.

*Sky Radiation and the Isothermal Layer:* F. W. VERY.

The author describes the mechanism of heat transference and radiation absorption in the atmosphere, referring to his work on "Atmospheric Radiation," pp. 114-115 and 124. Vapors are found in the atmosphere just so long as there remains a quantity of even the least absorbing gases sufficient to preserve the temperature above the vaporization point. It was pointed out in discussing the absorbing power of gases and vapors that the absorbing power of some gases was so feeble that many miles of absorbing layers were necessary to show the spectrum lines, while other lines, notably those of water vapor, are produced by the substances in very attenuated form. Water vapor is found at the altitude of 30 km., and since temperature inversion in the atmosphere is found everywhere associated with excessive amounts of aqueous vapor, there is no reason to doubt that the great region of permanent temperature inversion, the "isothermal layer," is due to this substance. The extreme tenuity of the vapor offers no difficulty to this supposition, since the layer is many kilometers deep. I have found the great Xi bands of aqueous vapor producing almost complete extinction of the solar spectrum through a range of 3 microns, when the temperature was  $-30^\circ \text{C}$ . This temperature is sometimes exceeded even in the isothermal layer, where also a relative humidity as high as 50 per cent. has been observed.

There are three principal loci of terrestrial radiation, namely: (1) a thin, heated, superficial layer of the terraqueous globe; (2) the solid or liquid particles suspended in the air; and (3) the upper static layer of air, called the isothermal

layer, in which the permanent temperature-inversion resides. The author's supposition that elevated regions of the atmospheric, up to something like 20 km., undergo much larger temperature-variations than the more deeply situated layers of the free air, has been confirmed by Blair's observations. This phenomenon also is attributed principally to absorption by aqueous vapors.

The earth's effective temperature is not that of an elevated layer of cool air, shown on the records of the meteorological stations, but a mean in varying proportions of the three loci named, which owe their temperature to a complex of radiation, convection, absorption, cloud precipitation, etc.

The general conclusion from sky measurements is that the effective sky-temperature is lower, on the whole, when the dew-point is lower, and the aqueous obstruction of radiation to space is least; but even in the coldest and driest weather, the sky temperature has never been found lower than that of the isothermal layer, which behaves like a nearly black body of approximate temperature,  $T = 218^\circ \text{ Abs. C.}$ ,  $\lambda \text{ max} = 13.5 \mu$ , and is opaque to most of the radiation from the solid earth of greater wave-length than this maximum.

*Orbits of the Visual and Spectroscopic Binary Star Epsilon Hydræ AB:* R. G. AITKEN.

The close double star known as  $\epsilon$  Hydræ AB, discovered by Schiaparelli in 1888, is unique among the visual binary systems in that the elements of its orbit can also be deduced from the spectrographic measures of the radial velocity.

A revised system of elements from the micrometer measures, which now cover an arc of  $450^\circ$ , gives 15.3 years as the best value for the revolution period. Adopting this as correct, the remaining elements were computed independently from the radial velocity measures, which extend from 1899 to 1911 and include both maximum and minimum values. It was possible to find a set of elements which would satisfy both series of observations within the error of observation. These elements are:  $P = 15.3 \text{ years} = 5,588 \text{ days}$ ;  $T = 1900.97 = \text{J.D.}$ ,  $2,415,375$ ;  $e = 0.65$ ;  $\omega = 90^\circ.0$ ;  $i = -49^\circ.95$ ;  $\Omega = 104^\circ.4$ ;  $a = 0''.23$ ;  $a \sin i = 493,000,000 \text{ km.}$ ;  $v = +36.78 \text{ km.}$ ;  $K = 8.45$ .

From these elements we find the mean distance between the two components of  $\epsilon$  Hydræ to be 1,359,000,000 km., or 9.1 astronomical units, the parallax of the system,  $0''.025$  and its mass, 3.33 times the sun's mass. Seeliger has shown that the periodic variations in the micrometer measures connecting the third star C with the close pair

can be accounted for by the orbital motion of the binary. Assuming the effective light center of  $AB$  to be one seventh of the distance from  $A$  toward  $B$ , he determines the mass ratio of the binary to be  $m'/m = 0.9$ .

Within the next five years the radial velocity will again reach both maximum and minimum values, and spectrographic observation during this interval will be of the greatest value in determining the orbit elements more precisely.

*International Standards of Wave-lengths:* C. E.

ST. JOHN and L. W. WARE.

This paper, which has appeared in full in the Contributions from the Mount Wilson Solar Observatory, No. 61, gives the results of the measurements of two series of plates of the iron arc spectrum, obtained with two plane grating spectrographs, one on Mt. Wilson and one in Pasadena. The precision obtained by interpolation between the international standards of the second order is 0.001 Ångström in the case of good lines. No errors were found in the relative wave-lengths of the secondary standards between  $\lambda 5371$  and  $\lambda 6494$  greater than 0.001 Ångström except for the line  $\lambda 5434$ , where it is 0.002 Å. In this region 44 lines were found unsuitable for standards of wave-lengths on account of pressure displacements accompanied with dissymmetry. Several lines showed differences in wave-length between the two series, bearing relation to the quality of line under pressure as shown on the plates of Gale and Adams.

*The Solar Rotation:* J. S. PLASKETT.

This paper presents the general results of a determination of the solar rotation for 1911 and a preliminary result for 1912. The values obtained at Ottawa for 1911 are well represented by the formulae

$$v = (1.483 + 0.532 \cos^2 \phi) \cos \phi, \\ \xi = 10^\circ.32 + 4^\circ.05 \cos \phi,$$

where  $v$  is the sidereal linear velocity of the reversing layer in km. per sec., and  $\xi$  the daily sidereal angular velocity,  $\phi$  the solar latitude. These are in remarkably good agreement with Duner's and Adams's 1908 values, except for a small angular difference constant for all latitudes. The formulae probably represent very closely the law of variation with latitude. Measures of the same plates by different observers give systematic differences of two or three per cent., indicating that the differences noted above are probably personal, and due to the character of the lines. The

discussion of some 3,000 residuals from different lines and elements show no systematic differences of velocity for different elements, or for different lines of the same element. No change greater than one per cent. is revealed in results for 1911 and 1912.

*The Spectroscopic System 9 Camelopardalis:* O. J.

LEE.

This star was announced as a binary by Frost and Adams\* from measures of the broad lines. They also found that the H and K lines, strong and narrow, give a variation which differs in phase and amplitude from that given by the other lines.

The observations cover about 3,000 days. The form of the velocity curve is incompatible with a simple two-body system and hence a certain form of calcium envelope has been assumed which both assists in reproducing the observed velocity curve and accounts for the difference in character of the broad lines and the calcium lines in the spectrum. The observed velocity curve is composed of three elements: the orbital velocity of the primary, the velocity of the calcium envelope about the center of the primary regarded as a stationary point, and the periodic eclipse of the spectroscopically effective parts of the envelope by the primary.

The elements of the stellar orbit are:  $P = 7.9957$  days,  $e = 0.30$ ,  $\mu = 45^\circ.024$ ,  $K = 9.0$ ,  $\omega = 90^\circ$  or  $270^\circ$  closely,  $T = \text{J.D. } 2,416,480.35$ ,  $\gamma = -2.25$  km.,  $i = 90^\circ$  nearly.

Assuming that the effective calcium clouds center about the two zero velocity points, which lie one on each side of the primary  $M/m = 2.85$  and  $M + m = 0.0023$ .

*The Rotation of Jupiter's First Satellite:* A. E.

DOUGLASS.

This satellite appears elliptical in form. A number of persons unacquainted with the identity of the satellites have been asked to select the one appearing elliptical. In fourteen out of seventeen trials the first has been picked out. The ellipticity is not constant, but varies on a period which does not seem to be constant. A hypothesis to account for the phenomena supposes the satellite to be an irregular body resembling an ellipsoid of three unequal axes in which the axis of figure has a considerable angle to the axis of rotation.

*The Light-curve of SS Cygni from the Amherst*

*Observations:* D. P. TODD and C. J. HUDSON.

Observations of this star and about 50 other

\* *Ap. J.*, 19, 350, 1904.

faint variables have, for the past two years, been regularly maintained with the 18-inch Clark refractor of the Amherst College Observatory. The observations are visual estimates and are accurate to tenth-magnitudes. They were much facilitated by the use of an external iris diaphragm, enabling the use of all apertures from 3 to 18 inches. The remarkable fluctuations of this star are represented on a diagram prepared by Mr. Hudson.

#### REPORTS OF COMMITTEES

Professor Campbell sent a written report from the Committee on Cooperation in the Measurement of Radial Velocities. The response of all the members of the committee was to the effect that though they might wish to cooperate, their instrumental resources were too weak to attack a long list of stars below the 5.0 visual magnitude where cooperation is desirable, and further, that fields of greatest usefulness for them consisted in the study of spectroscopic binaries or special groups of stars. In short, cooperation in the determination of radial velocities of extensive lists of stars fainter than the 5.0 mag. is at present impractical. The report ended with some hopeful suggestions.

The report of the Committee on Asteroids, sent by the chairman, Professor E. W. Brown, stated that the principal problems of those interested in the asteroids is to gather data for future discussion, the orbits, the light variations, etc. The first problem is the collection of the observations of position. Some organization to secure more nearly uniform observation of the many asteroids, to care for the new ones, to make certain the securing of a requisite number of early observations, to furnish an early orbit, should be perfected. An international conference on the asteroid problem is desirable.

The Committee on Comets, Professor G. C. Comstock, chairman, reported that the work of collecting data of photographic observations of Halley's comet was practically complete. The catalogue is ready for publication. The committee proposes to publish this together with the photographs secured by Mr. Ellerman at Honolulu.

Professor Schlesinger presented the report of the Committee on Photographic Astrometry. The 10-inch photographic telescope described in the last report has been mounted and put in operation. It is mounted in a constant temperature room having access to the polar region through a window of optically plane parallel glass. Exposures made from without and automatically timed on the

chronograph give very exact data for determining the polar point. The methods developed for measuring and reducing the plates were described and some numerical results presented. This work will be continued at least until the spring of 1913, by which time it is expected that definite knowledge will be secured concerning the movement of the pier mounted in this way.

The financial report showed an indebtedness of about \$200. Dr. John A. Brashear announced the purpose of certain Pittsburgh friends of the society to clear this indebtedness. This unprecedented generosity was gratefully acknowledged.

The report of the Committee on Teaching of Elementary Astronomy is of more general interest, so it is given in full.

*Report of Committee on Cooperation in Improvement of Teaching Elementary Astronomy:* C. L. DOOLITTLE, chairman. Report prepared by Miss Sarah F. Whiting.

Your committee was authorized at the Ottawa meeting to send out a circular to the observatories and colleges asking certain questions in reference to the teaching of elementary astronomy, and requesting suggestions as to methods of increasing the numbers in elementary courses, and improving the teaching.

A circular was sent out with the following preamble, to show the intent of the society:

"The Astronomical and Astrophysical Society of America states in its constitution that its purpose is the 'advancement of astronomy.'

"At its late meeting in Ottawa, Canada, it was mindful of the fact that the advancement of science depends not only on the discovery of new truth, but on the diffusion of knowledge, and the scientific spirit which creates a friendly atmosphere for its reception. The society considered the deplorable ignorance of persons, otherwise intelligent, in regard to the every-day phenomena of the sky, and the fact that astronomy lags behind the other sciences in adopting the modern method of laboratory work by the student."

Questions followed in reference to the beginning courses and methods of teaching.

Eighty replies were received, which may be considered representative, since twenty were from state universities, thirty from other universities and colleges of first rank, and thirty-two from smaller colleges and schools. Only ten reported a beginning course in astronomy extending through the academic year; thirteen reported two terms or a semester's work, and the other forty-two only

short lecture courses. Only thirty reported a regular program of evening observations, twelve some daytime exercises, ten some review of the elements of spectrum analysis as a basis for study of stellar classification, fourteen gave some library work, the rest gave only lectures with no laboratory work by the student. But two institutions, Harvard and Wellesley, reported two hours of daytime laboratory work by the students as in other sciences, and this in addition to evening work.

The numbers in the colleges electing an elementary course would be more significant if they could be reported in percentages, but this was not possible. That only eight universities and colleges reported a hundred and more in the first-year classes, three, 70-100, six, 50-70, and sixty-five mostly less than twenty-five, shows that a very small proportion of college men and women know much about anything off this little planet.

Special interest in the movement was emphatically expressed in more than half the replies, and the hope that the society can in some way bring its influence to bear to secure greater place for elementary astronomy in the programs of study, better methods of teaching elementary classes, and aid the teachers to secure better equipment and adequate assistance.

The leaders of the great research observatories, Harvard, Lick, Yerkes, Mt. Wilson, all expressed sympathy in the objects of the committee and the hope that astronomy would not long lag behind other sciences, taken up in liberal education. Several called attention to the fact that teachers of elementary astronomy should be trained as teachers of physics are trained. Colleges should be urged to understand that an observatory for the training of experts is not the entire equipment necessary for the work of a department of astronomy. Some replies, however, state the issue clearly from the standpoint of the heads of the departments of astronomy. In the choice between using the observatory for instruction or for research, the research problems have the stronger claims. As in other cases, the professor should be provided with adequate assistance.

The committee has brought the facts before the Society and calls for the assistance of the Society in constructive plans. The committee has no plan as yet formulated, but requests that it be continued.

PHILIP FOX,  
*Secretary*

## SOCIETIES AND ACADEMIES

### THE NEW ORLEANS ACADEMY OF SCIENCE

ON Tuesday, November 12, there was held at the Public Library the first regular meeting of the newly reorganized New Orleans Academy of Science. The New Orleans Academy of Science was founded in the year 1853, and was a vigorous society until the war, when its activities were suspended. It was revived again for a brief period soon after the war and then again in 1885, when it met regularly for about five years and published several volumes of transactions. Since 1890 the academy has been dormant.

As now reorganized it consists of sixteen sections with chairmen for each section as follows:

Biology and Physiology, Gustav Mann.  
Botany and Bacteriology, C. W. Duval.  
Zoology, George E. Beyer.  
Anthropology and Ethnology, R. B. Bean.  
Philology, Robert Sharp.  
History and Biography, Pierce Butler.  
Education, J. M. Gwinn.  
Economics and Sociology, A. P. Howard.  
Chemistry, Miss Ann Hero.  
Geology and Mineralogy, B. V. B. Dixon.  
Astronomy and Mathematics, A. B. Dinwiddie.  
Geography and Meteorology, J. A. Lyon.  
Engineering, W. H. P. Creighton.  
Physics, H. Clo.  
Philosophy, W. B. Smith.

The officers of the newly organized academy are:

*President*—William Benjamin Smith, professor of philosophy, Tulane University of Louisiana.

*First Vice-president*—Dr. Max Heller.

*Second Vice-president*—Dr. Isadore Dyer, dean of the medical department, Tulane University of Louisiana.

*Treasurer*—Dr. A. L. Metz, professor of chemistry, Tulane University of Louisiana.

*Secretary*—R. S. Cocks, professor of botany, Tulane University of Louisiana.

*Librarian and Curator*—Dr. Creighton Wellman, professor of tropical medicine and hygiene, including preventive medicine, Tulane University of Louisiana.

At the inauguration meeting there were addresses by the president and the two vice-presidents. The academy will meet hereafter the second Tuesday of each month.

R. S. COCKS,  
*Secretary*

# SCIENCE

NEW SERIES  
VOL. XXXVII. No. 941

FRIDAY, JANUARY 10, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

## Evolution of the Vertebrates and their Kin

By William Patten, Ph.D.,  
Professor of Zoology and Head  
of the Department of Biology  
in Dartmouth College, Han-  
over, N. H.

309 Illustrations. Sq. Oc-  
tavo. Cloth, \$4.50  
Postpaid.

It covers the entire range of  
animal forms in genetic se-  
quence; traces the evolution of  
the most important functions  
and explains the reasons for  
their shifting location in the  
body. The illustrations are  
based upon marvellously de-  
tailed preparations and give  
force to the unique suggestions  
of the author.

## Microbiology

A Text-book of Micro-  
organisms, General  
and Applied

By various writers. Edited  
by CHARLES E. MARSHALL,  
Professor of Microbiology and  
Director of Graduate School,  
Mass. Agricultural College.

129 Illustrations (1 Col-  
ored Plate) Flexible  
Cloth, \$2.50  
Postpaid.

Discusses Morphology, Cul-  
ture and Physiology of Micro-  
organisms, including Nutri-  
tion and Metabolism, Physical  
Influences; Bacteriology of  
Dairy, Soil, Water Supplies,  
Sewage Disposal, Air, Special  
Manufactures, Diseases of Man,  
Animals and Plants.

## Comparative An- atomy of the Vertebrates

By J. S. Kingsley, Professor  
of Biology in Tufts College,  
Massachusetts.

346 Illustrations. Octavo.  
Cloth, \$2.25 Post-  
paid.

This work is distinctly a  
Book for the Under-Graduate  
Student, and is intended to  
serve as a frame-work around  
which may be grouped the facts  
learned in the laboratory. Em-  
bryology has been made the  
basis, the various structures  
being traced from the undif-  
ferentiated egg into the adult  
condition. There has been no  
attempt to describe every spe-  
cies in detail, but rather to  
outline the general morphol-  
ogy of all vertebrates.

## Mammalian Anatomy

With Special Reference to  
the Cat.

2nd Edition. Revised

By Alvin Davison, A.M.,  
Ph.D., Professor of Biology,  
Lafayette College, Easton,  
Pennsylvania.

114 Illustrations. 12mo.  
Cloth, \$1.50 Post-  
paid.

"Furnishes an excellent  
idea of the structure of the cat,  
free from superfluity of de-  
tail."—*Science*.

## Zoology

2nd Edition

By T. W. Galloway, Pro-  
fessor of Biology, James Mil-  
liken University, Decatur,  
Illinois.

240 Illustrations. Octavo.  
466 Pages. Cloth,  
\$2.00 Post-  
paid.

"It is no small compliment  
to this volume to say that it  
is well balanced in its treat-  
ment of Zoology in the widest  
sense. . . . few recent text-  
books bear comparison with  
this volume."—*The Nation*.

## Elementary Zoology

By T. W. Galloway, Ph.D.  
Professor of Biology, James  
Milliken University, Decatur,  
Illinois.

160 Illustrations. Octavo.  
438 pages. Cloth,  
\$1.25 Post-  
paid.

"The material is excellently  
classified and of sufficient  
detail to get a young student  
thoroughly interested, if he  
has the slightest turn at all  
toward science."  
—*American Educ. Review*.

P. BLAKISTON'S SON & CO., Publishers  
1012 WALNUT STREET :: :: PHILADELPHIA

Smithsonian Institution  
JAN 11 1913

FOR COLLEGES, HIGH SCHOOLS  
PREPARATORY SCHOOLS  
AND PRIVATE OBSERVERS

THE MCKREADY MULTIPLE TELESCOPE  
(The Multiple Telescope is Protected by Letters Patent)

¶ The individual telescopes of the instrument are so adjusted to one another that their fields of view are coincident.

¶ As the fields of view are the same, an instructor stationed at the central or pilot telescope may free the beginner from initial difficulties, and may increase the pleasure and save the time of all concerned.

¶ The observer may take two students at once, one on either hand; and as he "finds" the object in the central telescope, it is found for them; as he "follows" the object and keeps it in the field, it is kept in field for them.

¶ Thus the students at the side telescopes have only to look; what the instructor sees, they see,—at the same instant, under the same conditions, and in the light of his immediate comment. Interesting detail can be pointed out, important principles can be illustrated in direct relation to objective examples; all phenomena can be understood more quickly and more clearly. Instruction is made coincident with observation.

¶ In the taking of students by twos instead of singly, there is a time-saving for the students who wait, as well as for the instructor who works. And the increased readiness and pleasure of comprehension add to the efficiency and cultural power of observation. Should the teacher desire the student at right or left to practice the control of the instrument, its direction may be yielded to either,—the three tubes being rigidly related to the common center.

¶ The tubes, however, are adjustable vertically and horizontally; they are instantly removable—to increase the ease with which the instrument may be carried about; and the connective mounting is also detachable from the tubes and tripod. When the mounting is adjusted for astronomical use at time of delivery by this Company, no readjustment is necessary in passing from moon to planet, or from planet to star.

¶ There is a sense of actuality in the direct observation of the things of the larger universe which cannot be given by a picture or by a lantern-slide. Ought not every High School, as well as every College, to have its Telescope? Prices from \$185.

¶ Kelvin McKready, designer and inventor of the Multiple Telescope, has produced in his "Beginner's Star-Book," a simple, practical telescopic manual—with star maps, observer's catalog, etc.

¶ It has been pronounced "the best" book in its field by such men as Sir David Gill, Puiseux, President of the Astronomical Society of France, Todd of Amherst, Russell of Princeton, Mitchell of Columbia, Brashers of Pittsburgh, Stone of the University of Virginia, and endorsed with equal warmth by Frost of Yerkes, Campbell of Lick, Max Wolf of Heidelberg, Beebe of Yale, and many others. Says W. Jevons, Department of Astrophysics of the Royal College of Science, South Kensington, London, "I shall take every possible opportunity to recommend the work to both teachers and students. It is the right thing with any course of evening demonstrations." Circulars and endorsements of "A Beginner's Star-Book" on request.

¶ Let us send you the Book (price \$2.50 net; by mail, \$2.75), with full descriptions of the Instrument. We sell other telescopes also, large and small; our catalog tells of them.

## THE CLEVELAND MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE sixty-fourth meeting of the American Association for the Advancement of Science was held at Cleveland, Ohio, from December 30, 1912, to January 4, 1913, under the presidency of Dr. Edward Charles Pickering, director of the Astronomical Observatory of Harvard College, Cambridge, Mass.

The excellent arrangements made for the meetings, the good hotel and other public utilities of Cleveland, and unusually mild and pleasant weather through most of the week, combined to make the material environment one of the most agreeable experienced by the association. The number of members registered was 720, and in addition 150 from the affiliated societies; but as is well known this registration is always incomplete, especially in the case of members of affiliated societies who are not members of the American Association for the Advancement of Science. It is safe to say that the total in attendance must have exceeded 1,000.

The following societies, most of them affiliated with the American Association for the Advancement of Science, met in Cleveland at the same time:

Astronomical and Astrophysical Society of America,  
 American Mathematical Society,  
 American Physical Society,  
 American Society of Zoologists, Eastern and Central Branches,  
 American Association of Economic Entomologists,  
 Entomological Society of America,  
 American Nature Study Society,  
 School Garden Association of America,  
 American Microscopical Society,  
 Botanical Society of America,  
 American Phytopathological Society,  
 Botanists of the Central States,  
 Society for Horticultural Science,  
 American Association of Official Horticultural Inspectors,  
 Association of Official Seed Analysts,  
 American Psychological Association,  
 American Society of Biological Chemists,  
 American Society for Pharmacology and Experimental Therapeutics,  
 American Association of Anatomists,  
 American Physiological Society,  
 American Federation of Teachers of the Mathematical and Natural Sciences,  
 Society of the Sigma Xi,  
 American Society of Naturalists.

The opening general session held on the evening of Monday, December 30, in the ball room of the Hotel Statler was called to order by the retiring president, Dr. Chas. E. Bessey, who introduced the president-elect, Dr. Edward C. Pickering. Addresses of welcome were given by Mr. Newton D. Baker, mayor of Cleveland, Dr. Chas. F. Thwing, president of the Western Reserve University, and Dr. F. M. Comstock, acting president of the Case School of Applied Science. Responses were made by President Pickering. The address of Mayor Baker was especially noteworthy as embodying ideals for the future of Cleveland which aroused the heartiest appreciation in the minds of all his hearers. Perhaps the strongest assurance that Cleveland will ultimately reach the eminent position predicted by him is the fact that it already

has the foresight to elect such men to its highest offices. The annual address was then delivered by the retiring president of the association, Dr. Charles Edward Bessey on "Some of the Next Steps in Botanical Science." It is printed in the issue of SCIENCE for January 3. The general session then adjourned and was followed by a reception to the members of the association and affiliated societies.

The annual addresses by retiring vice-presidents were made as follows:

### *Monday Afternoon*

Vice-president Shimek, before the Section of Geology and Geography. Title: "Significance of the Pleistocene Mollusks."

### *Tuesday Afternoon*

Vice-president Frost, before the Section of Mathematics and Astronomy. Title: "The Spectroscopic Determination of Stellar Velocities, Considered Practically."

Vice-president Nachtrieb, before the Section of Zoology. Title: "Section F—Is It Worth While?"

Vice-president Newcombe, before the Section of Botany. Title: "The Scope of State Natural History Surveys."

Vice-president Millikan, before the Section of Physics. Title: "Unitary Theories in Physics."

### *Wednesday Afternoon*

Vice-president Porter, before the Section of Physiology and Experimental Medicine. Title: "On the Function of Individual Cells in Nerve Centers."

Vice-president Thorndike, before the Section of Education. Title: "Educational Diagnosis."

Vice-president Ladd, before the Section of Anthropology and Psychology. Title: "The Study of Man."

*Thursday Afternoon*

Vice-president Norton, before the Section of Social and Economic Science. Title: "Comparative Measurements of the Changing Cost of Living."

Other addresses worthy of especial note were the following:

On Tuesday evening, Dr. W. J. Humphreys, of the U. S. Weather Bureau, gave an illustrated lecture, complimentary to the members of the American Association for the Advancement of Science and the affiliated societies and to the residents of Cleveland and vicinity, on the subject of "Across the United States with the European Geographers."

On Monday afternoon, President Benjamin M. Davis, of the American Nature Study Society, gave an address entitled "A Summary of the Study of Agricultural Instruction in Rural Schools."

President A. B. Macallum, of the American Society of Biological Chemists, gave an address on Monday on "The Energy of Muscular Contraction; Thermodynamic or Chemodynamic."

Dr. Edward Lee Thorndike gave his address on Tuesday, as president of the American Psychological Association, on the subject of "Ideo-motor Action."

President W. T. Macoun, of the Society for Horticultural Science, also gave his address on Tuesday on the subject "The Relation of Climate to Horticulture."

On Wednesday evening, Dr. Philip P. Calvert, of the Entomological Society of America, gave a public address on the subject "An Entomologist in Costa Rica."

On Wednesday, President W. D. Hunter, of the Society of Economic Entomologists, gave an address on the subject "Insects and Human Diseases."

On Wednesday afternoon, President John A. Lomax, of the Folk-Lore Society, gave an address on "Stories of an African Prince."

On Wednesday evening, Professor W. D. Farlow gave the address of the retiring president on "A Comparison of the Present Conditions in Botany with those in the Early Seventies."

On Thursday evening, Dr. T. J. Headlee gave his annual address, as president of the American Association of Official Horticultural Inspectors, on the subject of "The Federal Plant Quarantine Law."

On Thursday evening, Professor Edwin G. Conklin gave the annual address as president of the American Society of Naturalists on "Heredity and Responsibility."

A number of symposiums and sessions devoted to matters of public interest were held by various sections and affiliated societies. Among these may be mentioned a symposium under the auspices of the American Society of Biological Chemists on "Some Recent Applications of Physical Chemistry in Biology."

A symposium under the auspices of the Botanical Society of America on "Permeability and Osmotic Pressure."

A symposium by the Phytopathological Society on "International Phytopathological Problems."

A symposium in charge of the American Society of Naturalists on "Adaptation."

The section on social and economic science held a symposium on some economic problems of current interest.

A general interest program on sound and sound waves was held under the auspices of Section B.

A general interest program devoted largely to broad educational problems, including a discussion of the National University was held under the auspices of Section L.

The council met daily. Among the chief matters of business transacted were the following:

Seventy-five new members were elected.

Two hundred and fifty-five members were elected fellows.

A report from the committee on policy was adopted, providing for the appointment of a committee of five to consider the future of Section C.

The amendment to the constitution, proposed last year, and providing for the establishment of "Section M. Agriculture," was adopted.

Amendments to the constitution were also proposed as follows, in order that they may be acted upon next year under the provisions of the constitution.

Article 22—Amend by omitting "*Mechanical and*" after the title "*D*," so as to read; "*D—Engineering.*"

Article 22—After "Section M. Agriculture" add "*The council shall have power to create additional sections from time to time, and to discontinue, combine, or rearrange existing sections.*"

The financial report of the permanent secretary was read, accepted and ordered printed.

The council adopted the following resolutions, relating to the proposed meeting at San Francisco in 1915.

*Resolved:* that a committee be appointed for the proposed San Francisco meeting of the association in 1915, this committee to be known as "The Committee on the Pacific Coast Meeting."

The president later appointed on this committee the following:

Wm. Wallace Campbell, Sc.D., LL.D., director of the Lick Observatory, Mt. Hamilton, Cal., *chairman*; John Casper Brauner, Ph.D., LL.D., professor of geology, Leland Stanford University; Wm. Alanson Bryan, president Pacific Scientific Institution, Honolulu; Henry Smith Carhart, Sc.D., LL.D., Pasadena, Cal.; Charles Lincoln Edwards, Ph.D., University of Southern California, Los Angeles, Cal.; Professor Wm. Trufont Foster, president of Reed College, Portland, Ore.; Geo. Ellery Hale, Sc.D., LL.D., director of the Mt. Wilson Observatory, Pasadena, Cal.; Mellen Woodman Haskell, Ph.D., professor of mathe-

atics, University of California; Eugene Walde-mar Hilgard, Ph.D., emeritus director of the College of Agriculture, University of California; Geo. Holmes Howison, LL.D., professor of philosophy, University of California; Oliver Peebles Jenkins, professor of physiology, Stanford University; David Starr Jordan, M.D., Ph.D., LL.D., president of Stanford University; Thos. Franklin Kane, Ph.D., president of the University of Washington; Lyman Vernon Kellogg, professor of entomology, Stanford University; Chas. Atwood Kofoid, Ph.D., professor of zoology, University of California; Alfred L. Kroeber, Ph.D., Affiliated Colleges, San Francisco, Cal.; Andrew Cowper Lawson, professor of geology and mineralogy, University of California; E. Percival Lewis, Ph.D., professor of physics, University of California; Jas. Harvey McBride, M.D., Pasadena, Cal.; Daniel Trembly McDougal, Ph.D., LL.D., Desert Botanical Laboratory, Tucson, Ariz.; Lillian J. Martin, professor of psychology, Stanford University; John Campbell Merriam, Ph.D., professor of paleontology, University of California; Agnes Claypool Moody, Ph.D., Berkeley, Cal.; John Muir, LL.D., Martinez, Cal.; Wm. Emerson Ritter, Ph.D., director of the Marine Biological Station, San Diego, Cal.; Harris Joseph Ryan, professor of electrical engineering, Stanford University; Fernando Sanford, professor of physics, Stanford University; William Albert Setchell, Ph.D., professor of botany, University of California; John M. Stillman, Ph.D., professor of chemistry, Stanford University; Benjamin Ide Wheeler, president of the University of California.

The committee on policy presented the following, which was adopted:

*Resolved:* that it be recommended that the council authorizes the committee on the Pacific Coast meeting proposed for 1915, to hold in the name of the association meetings of its members resident in that region, for the purpose of considering the relations of the association to the exposition in question, and if desirable, for the presentation of scientific programs. The expenses incurred shall be met from funds in the hands of the permanent secretary to such extent as may be approved by the committee on policy.

The following grant was allowed:

To the Concilium Bibliographicum . \$200

A report of progress in the study of fish scales was received from Prof. Theo. D. A.

Cockerell to whom a grant of \$75.00 had been made.

A report was received from Mr. Charles Peabody, delegate of the association to the XIV. Congress International d'Anthropologie et Archeologie Prehistorique, which was held in Geneva, September 9-14, 1912.

The council passed the following resolution on "Expert Testimony," presented jointly by Dr. M. G. Lloyd and Dr. J. A. Holmes:

*Resolved:* that a special committee of five be appointed by the president to collect and study data covering the practise in different countries relative to the employment of expert testimony in court procedure, and to cooperate in joint committee with representatives of other national organizations in studying this question with a view to submitting recommendation for new state and national legislation concerning the same;

That the permanent secretary of the association extend to other national organizations interested in this subject an invitation from this association to appoint a member on said joint committee, and to cooperate further with this association in taking such action relative to this matter as will best promote public interest;

That this social committee of five shall report both its findings and the findings of the joint committee, and also such action as may be taken by other organizations to the council of the American Association for the Advancement of Science at its meeting in January, 1914.

The council adopted the following, introduced by Professor H. B. Ward:

*Resolved:* That the council refer to the committee on policy the question of granting to secretaries of sections, the general secretary, and the secretary of the council, a mileage allowance in addition to the hotel allowance now made, and that the council empower the committee to take such action as may seem wise after investigation of the subject.

The following resolution, introduced by Dr. J. A. Holmes, was adopted by the council:

*Resolved:* that a special committee of five be appointed by the president to consider and report

to the committee on policy a plan for the more rapid increase in the membership of the association.

That the committee on policy is hereby authorized to employ an associate secretary at a salary not to exceed \$3,000 per annum, whose traveling expenses shall also be paid out of the treasury not to exceed \$800 per annum and whose special duty it shall be to carry forward this extension work.

The committee on policy is hereby authorized to adopt, if necessary, such method as it may deem best for collecting additional funds for meeting such expenditure as may be needed.

The president later appointed on this committee the following: Messrs. J. A. Holmes, Chas. Baskerville, Hugh M. Smith, H. B. Ward, H. W. Springsteen.

The council adopted the following resolutions, introduced by Dr. J. McK. Cattell:

*Resolved:* that the council of the American Association for the Advancement of Science requests the educational institutions, government bureaus and other agencies engaged in scientific research to send one or more delegates to the annual convocation week meetings of the association and its affiliated societies, and that when possible the traveling expenses of the delegates be paid by the institutions which they represent.

*Resolved:* that a committee of three be appointed by the chair to draw up a list of institutions to which this resolution, together with a suitable letter, shall be sent by the permanent secretary.

The following were elected as members of the council to serve for three years: Messrs. J. McK. Cattell, J. M. Coulter and N. L. Britton.

At a meeting of the general committee held Thursday evening, January 2, invitations for future meetings were received from Atlanta, Philadelphia, Nashville, St. Louis, San Francisco, Leland Stanford, University of California, Portland, Seattle, Niagara Falls, Cincinnati, Columbus and Denver.

It was resolved to hold the next meeting in Atlanta, Georgia. It was further resolved to recommend to the next general committee that the meeting for 1914 be

held at Philadelphia, and that a summer meeting be held at San Francisco in 1915.

The following officers were elected for the coming year:

*President:* E. B. Wilson, Columbia University, New York.

*Vice-Presidents:*

Section A—Frank Schlesinger, Allegheny Observatory.

Section B—A. D. Cole, Ohio State University.

Section C—A. A. Noyes, Massachusetts Institute of Technology.

Section D—O. P. Hood, U. S. Bureau of Mines, Washington, D. C.

Section E—J. S. Diller, U. S. Geological Survey.

Section F—A. G. Mayer, Carnegie Institution of Washington.

Section G—H. C. Cowles, University of Chicago.

Section H—W. B. Pillsbury, University of Michigan.

Section L—P. P. Claxton, U. S. Commissioner of Education.

*General Secretary:* H. W. Springsteen, Western Reserve University.

*Secretary of the Council:* W. A. Worsham, Jr., University of Georgia.

*Secretaries of Sections:*

Section A—F. R. Moulton, University of Chicago.

Section D—A. H. Blanchard, Columbia University.

Section F—H. V. Neale, Knox College.

Section G—W. J. V. Osterhout, Harvard University.

Section H—George G. MacCurdy, Yale University.

Section L—S. A. Courtis, Detroit, Michigan.

Place of next meeting: Atlanta, Georgia.

Date of next meeting: Convocation Week, 1913-14.

At the general session, held Friday morning at Western Reserve University, the following resolutions were adopted:

*Resolved:* that the American Association for the Advancement of Science extend to the authorities of Western Reserve University and to those of the Case School of Applied Science, to the Board of Education and the Director of Public Schools, to the Mayor of Cleveland, to the local committee in charge of the arrangements for the third Cleveland

meeting of the association, now about to close, and especially to the ladies' reception committee and to the authorities of the different industrial plants which have been opened to the inspection of members, the hearty thanks of the association for the admirable arrangements made, the excellent facilities offered, and the delightful courtesy and hospitality which have been extended by all and which have been highly instrumental in making this third Cleveland meeting one of the most successful which the association has held in recent years.

H. E. SUMMERS,  
*General Secretary*

#### HEREDITY AND RESPONSIBILITY<sup>1</sup>

ONE of the greatest and most far-reaching themes which has ever occupied the minds of men is the problem of development. Whether it be the development of a chicken from an egg, of a race or species from a preexisting one, or of the body, mind and institutions of man, this problem is everywhere much the same in fundamental principles, and knowledge gained in one of these fields must be of value in each of the others. Familiarity with development does not remove the real mystery which lies back of it, though it may make plain many of the processes concerned. The development of a human being, of a personality, from a germ cell seems to me the climax of all wonders, greater even than that involved in the evolution of a species or the making of a world.

We are all familiar with the historic attempts which have been made to solve this problem. The old doctrine of evolution, or preformation, solved it by practically denying development; the doctrine of epigenesis recognized development but did not explain it. The one found all organs and parts present in the germ, which needed merely to grow and unfold to bring them

<sup>1</sup>Presidential address before the American Society of Naturalists, Cleveland, O., January 2, 1913.

to maturity; the other found the germ simple and homogeneous, but required some unknown force, some *spiritus rector* or *vis essentialis*, to cause the homogeneous to become heterogeneous. The one placed all emphasis upon the germ, the other upon outside forces or conditions.

Modern students of development recognize that neither of these extreme views is true—adult parts are not present in the germ, nor is the latter homogeneous—but for more than a hundred years opinions have been vibrating in the field between these two extremes.

Students of development, whether it be that of the individual or of the race, are like those ancient mariners who sailed that dreaded strait on the one side of which frowned Scylla and on the other roared Charybdis—in shunning the Scylla of preformation they run into the Charybdis of epigenesis, in avoiding the rocks of predetermination they fall into the whirlpools of no-determination, in avoiding the perils of fatalism they encounter the dangers of chaotic freedom—while the narrow channel of truth runs somewhere between these two extremes. They tack from one side to the other, ever advancing, ever leaving old dangers behind, ever meeting new ones—and so the science of development zig-zags on.

At present there can be no doubt that we are sailing nearer the preformation coast than at any time since the modern study of development began under von Baer. In the study of heredity great emphasis is placed, and necessarily so, upon the complexity of the germ and the intrinsic factors of development. There can be no doubt that the main characteristics of every living thing are unalterably fixed by heredity. Men differ from horses or turnips because of their inheritance. Our anatomical, physiological and psycho-

logical possibilities are predetermined in the germ cells. Whatever the ultimate relations of mind and body may be, there can be no reasonable doubt that both have developed together from the germ and that the laws of inheritance apply to one as certainly as to the other. The main characteristics of our personalities are born with us and can not be changed except within relatively narrow limits. "The leopard can not change his spots nor the Ethiopian his skin," and "though thou shouldst bray a fool in a mortar with a pestle yet will not his foolishness depart from him." Race, sex, character are predetermined in the germ cells, perhaps in the chromosomes, and all the possibilities of our lives are there fixed, for who by taking thought can add one chromosome, or even one determiner, to his organization?

These modern theories of heredity are profoundly influencing human thought in many fields. We formerly heard that all men were created free and equal; we now learn that all men are created bound and unequal. We were once taught that voluntary acts, if oft repeated, become habits, and that habits determine character; we now learn that acts, habits and character were foreordained from the foundation of the family. We once thought that men were free to do right or wrong, and that they were responsible for their deeds; now we learn that our reactions are predetermined by heredity and that we can no more control them than we can control our heart beats. For ages men have believed in the influence of example, in the uplift of high ideals, in the power of an absorbing purpose; for ages men have lived and died for what they believed to be duty and truth, and have received the homage of mankind; or they have lived malevolent and criminal lives and have been despised

by men and punished by society. But if our reactions, habits, characters are predetermined in the germ plasm such men have deserved neither praise nor blame. If personality is determined by heredity alone, all teaching, preaching, government, is useless; freedom, responsibility, duty are delusions; whether men are useful or useless members of society depends upon their inheritance, and the only hope for the race is in eugenics—always supposing that enough freedom is left to men or to society to control the important function of choosing a mate.

Already a few enthusiastic persons have begun to apply these doctrines to practical affairs. We are told that children should never be admonished or punished, for they do only what their natures lead them to do; the nature of the child must be respected and must be allowed to manifest itself in its own way. Lying and stealing will cure themselves like the mumps, or they will remain incurable, in which case the germ plasm is to blame and nothing could have been done, anyway. Laziness is due to inheritance or to parasites; the latter kind may be cured, but not the former. Thriftlessness, alcoholism and uncleanness run in families and can be cured only by extermination. Men who prey upon society were born with wolfish instincts, and can not help but eat the lambs. Villains, lawbreakers, murderers should be pitied but not punished; if blame attaches to their deeds it falls upon the marriage bureau and the parents. The world needs hospitals and sanatoria and sterilization institutes for the criminals and vicious, but not courts and prisons, and all punishments should be visited only upon the parents to the third and fourth generations.

Do our studies of heredity lead us to any such radical conclusions? If they do

we must accept them like brave men. "Truth is truth if it sears our eyeballs." But when theories lead to such revolutionary results it behooves us to examine carefully those theories to see if there is not somewhere a fundamental flaw in them. Have we not sailed a little too close to the preformation coast and grounded our ship on the rocks of predetermination?

One of the most difficult things in the world is to recognize a great truth, to feel its significance, and yet not be carried away by it. Great scientific errors are frequently due not so much to faulty observations as to sweeping conclusions. In biology the search for universal laws is a peculiarly dangerous pursuit. In philosophy great errors are often due not so much to false premises as to supposed logical necessities. A logical chain has led many a man into the bondage of error. Truth is not usually found in extremes, in "carrying out a process to its logical conclusions," but rather in some middle course which is less striking but more judicious.

Having observed that the main characteristics of our minds as well as of our bodies are inherited, it is easy and natural to go further and to conclude that not only all the possibilities of our lives are marked out in the germ, but that all that will actually develop from the germ is there determined and can not be altered. There are many similarities between such an extreme view and the old doctrine of preformation, and it contains a like absurdity. It practically denies development altogether. If the germ is a closed system and receives nothing from without, and if adult characteristics are predetermined in the germ, they are as irrevocably fixed as if they were predelineated.

At the opposite extreme is the view with which we are all familiar, viz., the will is absolutely free; no taint of heredity rests

on the mind or soul; character is a *tabula rasa* on which the self writes its own record as it pleases and is responsible for the result. This view, like the old epigenesis, virtually postulates a new creation for each individual. So far as the mind and soul are concerned there is no hereditary continuity with past generations and none with future ones. But while such a view may be logically complete and theologically satisfying, it is not scientific, for it contradicts the evidence.

The truth then seems to lie somewhere between these two extremes. Our personalities were not absolutely predetermined in the germ cells from which we came, and yet they have arisen from those germ cells and have been conditioned by them. When it is said that any characteristic is predetermined in the germ cell, what does this mean? What but that the development of that characteristic is made possible? Adult characteristics are potential and not actual in the germ, and their actual appearance depends upon many complicated reactions of the germinal units with one another and with the environment. In short, our actual personalities are not predetermined in the germ cells, but our possible personalities are.

In all organisms the potentialities of development are much greater than the actualities. In many animals a small part of the body is capable, when separated from the remainder, of producing a whole body, though this potency would never have become an actuality except under the stimulus of separation. In like manner a part of an egg may, when separated from the remainder, give rise to an entire animal. By modifying the conditions of development animals may be produced which have one eye, many eyes, or no eyes; animals in which the bodies are turned inside out or side for side; animals in which all

sorts of dislocation of organs have taken place; and the earlier the environmental forces act the more profound are the modifications produced. But leaving out of account all forms which are so monstrous that they are incapable of reaching maturity, we find that there are left many variations in the size and vigor of the body as a whole, as well as of its parts; many variations in the more or less perfect correlation of these parts with one another, which were determined by the conditions of development rather than by heredity. In a given germ cell there is the potency of any kind of organism that could develop from that cell under any kind of conditions. The potencies of development are much greater than the actualities. Anything which could possibly appear in the course of development is potential in heredity, and under given conditions of environment is predetermined. Since the environment can not be all things at once, many hereditary possibilities must remain latent or undeveloped. Consequently the results of development are not determined by heredity alone, but also by extrinsic causes. Things can not be predetermined in heredity which are not also predetermined in environment.

Functional activity, or use, is one of the most important factors of development. Functional activity is response to stimuli, which may be external or internal in origin. The entire process of development may be regarded as an almost endless series of such responses on the part of the organism, whether germ cell, embryo, or adult, to external and internal stimuli. It is a truism that use strengthens a part and disuse weakens it; it is likewise a truism that responses which are oft repeated become more rapid and more perfect, and in this way habits are formed. Practically all education, whether of man or of lower ani-

mals, consists in habit formation, in establishing constant relations between certain external or internal stimuli and certain responses of the organism. At first these stimuli are largely of external origin; later the external stimuli may be replaced more and more by internal ones; but whatever the source of the stimulus, the response of the organism to these stimuli is one of the most important factors of development, whether of the body or of the mind.

Among organisms a given cause does not always produce the same effect; this does not necessarily involve any violation of the law of causality, since it is highly probable that in responding to a stimulus the organism itself undergoes some change, and in subsequent repetitions of the stimulus, responses may differ because the organism is itself different. This is what is meant by "summation of stimuli," "physiological states," etc. Even in some of the simplest organisms one can observe inhibitions of responses and modifications of behavior, which seem to be due to conflicting stimuli, or to changes in the physiological state. In higher organisms such inhibitions or modifications proceed particularly from internal stimuli, which in turn are probably conditioned by hereditary constitution and past experience. The factors which determine behavior are not merely the present stimulus and the hereditary constitution, but also the experiences through which the organism has passed and the habits which it has formed.

By responsibility in the higher sense I understand the ability on the part of the individual to respond to rational, social and ethical stimuli, or impulses, and to inhibit responses to stimuli of an opposite nature; and the corresponding expectation on the part of others that the individual will so respond. The higher the type of organization the larger is the range

of stimuli to which it will respond and the larger the number and kind of responses which may be called forth; and at the same time the larger becomes the power of inhibition of responses, whether through the balancing of one stimulus against another or from whatever cause. Human responsibility varies with the complexity of the stimuli involved, as well as with the capacity of individuals to respond to those stimuli. A man might be quite responsible in savage society, who would be quite irresponsible in civilized communities. In an infant there is no capacity to respond to rational, social or ethical stimuli, but with increasing capacity in this respect comes increasing responsibility. Mental and ethical imbeciles, insane and mentally defective persons, have a low capacity for such responses and inhibitions, and consequently less is expected of them. There are in different men all degrees of responsibility, as there are all degrees of capacity. In one and the same individual responsibility varies at different times and under different circumstances; it rises and falls, like the tides, in every life. Varying capacity to respond to rational, social and ethical stimuli, and to inhibit responses of an opposite nature depends not merely upon inheritance, but also upon training, habits, physiological states. The common opinion that all normal men are equally responsible is not correct; in the eyes of the law this may be true, but legal obligations are so far below the capacities of normal men that all may be held equally responsible before the law, though in reality their responsibilities are as varied as their inheritance or their training.

Conversely the responsibility of society to the individual is universally recognized. Irresponsible persons must be cared for by older or wiser persons who become responsible for them; and in general the responsi-

bility rests upon society to provide as favorable environment as possible for all its members. Experienced persons can to a certain extent choose their own environment and thus indirectly control their responses and habits, but young children are almost, if not quite, as incapable of choosing their environment as of choosing their heredity, and it becomes the duty of society to see to it that the environmental stimuli are such as to develop rational, social and ethical habits rather than the reverse.

Of all animals I suppose that man enjoys the most extensive and most varied environment, and its effect upon his personality is correspondingly great. Of all animals man has the longest period of immaturity and it is during this period that the play of environmental stimuli on the organism is effective in modifying development. In addition to the material environment he lives in the midst of intellectual, social and moral stimuli which are potent factors in his development. By means of his power to look before and after he lives in the future and past as well as in the present; through tradition and history he becomes an heir of all the ages. The modifying influences of all these environmental conditions on personality is very great. Each of us may say with Ulysses: "I am a part of all that I have met." So great is the power of environment on the development of personality that it may outweigh inheritance; a relatively poor inheritance with excellent environmental conditions often produces better results than a good inheritance with poor conditions. Of course no sort of environment can do more than to bring out the hereditary possibilities, but, on the other hand, those possibilities must remain latent and undeveloped unless they are stimulated into activity by the environment.

Not only the possibilities of development, but also the actual, developed capacities of men, are much greater than the habitual demands which are made upon them. How often have we surprised ourselves by doing some unusual or prodigious task! What we have once done we feel that we can do again. We realize more or less clearly, depending upon our experience, that what we habitually do is far less than we could do. It is this reserve, upon which we can draw on special occasions, that gives us the sense of freedom. I well remember a conversation which I once had with the late Dr. William Pepper. He had asked me to undertake a task which I felt incapable of performing, and I had pleaded inability, lack of time, anything to escape the responsibility. But with a confidence born of experience he said to me, "You know we *can* do what we *have* to do." In his inspiring address on "The Energies of Men," William James showed that we have reservoirs of power which we rarely tap, great energies upon which we seldom draw, and that we habitually live upon a level which is far below that which we might occupy. Darwin held the opinion, as the result of a lifetime of observation, that men differ less in capacity than in zeal and determination to utilize the powers which they have. In playful comment on the variety and extent of his own life work he said, in modest and homely phrase, "It is dogged as does it." It may be objected that the zeal and determination were inherited, but here also the hereditary possibilities become actualities only as a result of use, training, habit.

It is generally admitted that no constant distinction can be recognized between the brain of a philosopher and that of many a peasant. Neither size nor weight of brain, nor complexity of convolutions, bears any constant relation to ignorance or intelli-

gence, though doubtless an "unlimited microscopist" could find differences between the trained and the untrained brain. The brains of Beethoven, Gauss and Cuvier, although unusually large, have been matched in size and visible complexity by the brains of unknown and unlearned persons—persons who were richly endowed by nature, but who had never learned to use their talents. In all men the capacity for intellectual development is probably much greater than the actuality. The parable of the talents expresses a profound biological truth: men differ in hereditary endowments, one receives ten talents and another receives but one; but the used talent increases many fold, the unused remains unchanged and undeveloped. Happy is he who is compelled to use his talents; thrice happy he who has learned how to compel himself! We shall not live to see the day when human inheritance is greatly improved, though that time will doubtless come, but in the meantime we may console ourselves by the thought that we have many half-used talents, many latent capacities, and although we may not be able to add to our inheritance new territory, we may greatly improve that which we have.

I have once or twice in this address referred to eugenics in a way which was intended to be facetious, but I would not wish to be understood as attempting to disparage that infant industry. Undoubtedly it represents an important application of biological discoveries to human welfare; but it seems to me that it can not wisely go farther at this time than to attempt to eliminate from reproduction the most unfit members of society. Giving advice regarding matrimony is proverbially a hazardous performance, and it is not much safer for the biologist than for others. With a more complete knowledge with regard to the in-

heritance of human defects than we now possess, at least in many instances, it will probably be possible to give such advice wisely; but apart from certain bodily peculiarities, he would be a bold prophet who would undertake to predict the type of personality which might be expected in the children of a given union. Some very unpromising stocks have brought forth wonderful products. Could any one have predicted Abraham Lincoln from a study of his ancestry? Observe I say *predict*, and not explain after his appearance. Can any one now predict from what kind of ancestral combinations the great scholars, statesmen, men of affairs of the next generation will come? Could the capacities and careers of the members of this society—those who were born outside of Boston or Philadelphia—have been predicted? The time may come when it will be possible to predict what the chances are that the children of given parents will inherit more or less than average intellectual capacity, but since germinal potentiality is transformed into intellectual ability only as the result of development, such a prediction could not be extended to the latter unless the environment as well as the heredity were known. Society can safely eliminate its worst elements from reproduction, but it can not wisely go farther than that at present.

My distinguished predecessor in this office, in his striking address before this society one year ago, pointed out as one of the great tragedies of life the almost infinite slaughter of potential personalities in the form of germ cells which never develop. A more dreadful, though less universal, tragedy is the loss of real personalities who have all the native endowments of genius and leadership, but who for lack of proper environmental stimuli have remained undeveloped and unknown; the "mute, inglorious Miltons" of the world; the Cæsars,

Napoleons, Washingtons who might have been; the Newtons, Darwins, Pasteurs who were ready formed by nature, but who never discovered themselves. One shudders to think how narrowly Newton escaped being an unknown farmer, or Faraday an obscure bookbinder, or Pasteur a provincial tanner. In the history of the world there must have been many men of equal native endowments who missed the slender chance which came to these. We form the habit of thinking of great men as having appeared only at long intervals, and yet we know that great crises always discover great men. What does this mean but that the men are ready formed and that it requires only this extra stimulus to call them forth? To most of us heredity has been kind—kinder than we know. The possibilities within us are great but they rarely come to full epiphany.

What is needed in education more than anything else is some means or system which will train the powers of self discovery and self control. Easy lives and so-called "good environment" will not arouse the dormant powers. It usually takes the stress and strain of hard necessity to make us acquainted with our hidden selves, to rouse the sleeping giant within us. How often is it said that the worthless sons of worthy parents are mysteries; with the best of heredity and environment they amount to nothing; whereas the sons of poor and ignorant farmers, blacksmiths, tanners and backwoodsmen, with few opportunities and with many hardships and disadvantages become world figures. Probably the inheritance in these last-named cases was no better than in the former, but the environment was better. "Good environment" usually means easy, pleasant, refined surroundings, "all the opportunities that money can buy," but little responsibility and none of that self discipline which re-

veals the hidden powers, and which alone should be counted good environment. Many schools and colleges are making the same mistake as the fond parents; luxury, soft living, irresponsibility are not only allowed, but are encouraged and endowed—and by such means it is hoped to bring out that in men which can only be born in travail. College athletics has this much at least in its favor, that it trains men who take part in the contests to do their best, to subordinate pleasure, appetite, the desire for a good time, to one controlling purpose, it trains them to attempt what may often seem to them impossible, to crash into the line though it may seem a stone wall, to get out of their bodies every ounce of strength and endurance which they possess. Such training makes men acquainted with their powers and teaches courage, confidence and responsibility. If only we could make young persons acquainted in some similar way with their hidden mental and moral powers, what a race of men and women might we not have without waiting for that uncertain day when the inheritance of the race will be improved! Whatever the stimulus required, whether pride or shame, fear or favor, ambition or loyalty, responsibility or necessity, education should utilize each and all of these to teach men self knowledge and self control.

But it will be said that self control depends upon inheritance, that strong wills and weak wills are such because of heredity. It is true that one man may be born with a potentiality for self control which another man lacks, but in all men this potentiality becomes actuality only through development, one of the principal factors of which is use, or functional activity. An amazing number of persons have but little self control. Is this always due to defective inheritance, or is it not frequently the result of bad habits, of arrested develop-

ment? To charge defects at once to heredity removes them from any possible control, helps to make men irresponsible, excuses them for making the least of their endowments. To hold that everything has been predetermined, that nothing is self determined, that all our traits and acts are fixed beyond the possibility of change is an enervating philosophy and is not good science, for it does not accord with the evidence. It is amazing that men whose daily lives contradict this paralyzing philosophy still hold it, as it were, in some water-tight compartment of the brain, while in all the other parts of their being their acts proclaim that they believe in their powers of self control: they set themselves hard tasks, they overcome great difficulties, they work until it hurts, until they can say with Johannes Müller, "Es klebt blut an der Arbeit," and yet in the philosophical compartment of their minds they can say that it was all predetermined in heredity and from the foundations of the world. Whether all the phenomena of life and of mind can be explained on the basis of a purely mechanistic hypothesis or not, that hypothesis must square with the facts and not the facts with the hypothesis. It has always been true of those who "sat apart and reasoned high of fate, free will, foreknowledge absolute" that they have "found no end in wandering mazes lost." Whatever the way out of these mazes may be—whether it be found in the varied responses of an organism to the same stimulus, in the immense complexity of the mechanism involved, or in some form of idealism which finds necessity not in nature but in the spectator, and freedom not in the spectator but in the agent—it is true that for those who do not "sit apart and reason high," but who deal merely with evident phenomena, the way out of these mazes is not to be found in denying the actuality of inhibition, attention, and con-

trol. Because we can find no place in our philosophy and logic for self determination shall we cease to be scientists and close our eyes to the evidences? The first duty of science is to appeal to fact, and to settle later with logic and philosophy. Is it not a fact that the possibilities of our inheritance depend for their realization upon development, one of the most important factors of which is use, functional activity, in response to stimuli? Is it not a fact that our capacities are very much greater than our habitual demands upon them? Is it not a fact that belief in our responsibility energizes our lives and gives vigor to our mental and moral fiber? Is it not a fact that shifting all responsibility from men to their heredity or to that part of their environment which is beyond their control helps to make them irresponsible?

This debilitating philosophy in which everything is predetermined, in which there is no possibility of change or control, in which there is hypertrophy of intellect and atrophy of will, is a symptom of senility, whether in men or nations. We need to return to the joys of a childhood age in which men believed themselves free to do, to think, to strive, in which life was full of high endeavor and the world was crowded with great emprise. We need to think of the possibilities of development as well as of the limitations of heredity. Chance, heredity, environment have settled many things for us; we are hedged about by bounds which we can not pass; but those bounds are not so narrow as we are sometimes taught, and within them we have a considerable degree of freedom and responsibility.

That which we are we are,  
 One equal temper of heroic hearts  
 Made weak by time and fate, but strong in will  
 To strive, to seek, to find, and not to yield.

EDWIN G. CONKLIN  
 PRINCETON, N. J.

## SCIENTIFIC NOTES AND NEWS

PROFESSOR E. B. WILSON, of Columbia University, was elected president of the American Association for the Advancement of Science at the Cleveland meeting. A report of the meeting and a list of the other officers elected will be found above. National scientific societies meeting at Cleveland elected presidents as follows: The American Physical Society, Professor B. O. Peirce, of Harvard University; the American Botanical Society, Professor D. H. Campbell, of Stanford University; the American Psychological Association, Professor C. H. Warren, of Princeton University; the Society of the Sigma Xi, Professor J. McKeen Cattell, of Columbia University; the American Society of Naturalists, Professor Ross G. Harrison, of Yale University.

At the annual election of the American Philosophical Society held on January 3, 1913, the following were elected:

*President:* William W. Keen.

*Vice-presidents:* William B. Scott, Albert A. Michelson, Edward C. Pickering.

*Secretaries:* I. Minis Hays, Arthur W. Goodspeed, Amos P. Brown, Harry F. Keller.

*Curators:* Charles L. Doolittle, William P. Wilson, Leslie W. Miller.

*Treasurer:* Henry La Barre Jayne.

*Councillors:* Charlemagne Tower, William Morris Davis, George Ellery Hale, R. A. F. Penrose, Jr., Samuel W. Pennypacker.

THE eighty-first annual meeting of the British Medical Association will be held in Brighton beginning July 22. Dr. W. A. Hollis, consulting physician, Sussex County Hospital, is the president-elect. The address in medicine will be delivered by Professor G. R. Murray, physician to the Royal Infirmary, Manchester. The address in surgery will be delivered by Sir Berkeley Moynihan, professor of clinical surgery in the University of Leeds. The popular lecture will be delivered by Mr. E. J. Spitta.

THE John Fritz medal, awarded annually by the four great engineering societies, has been awarded this year to Mr. Robert Woolston Hunt for his contributions to the development of the Bessemer steel process.

THE Academy of Medicine, Paris, has elected Professor Delezenne an honorary member of the section on anatomy and physiology to fill the vacancy caused by the death of Professor Marc Sée.

DR. W. E. BYERLY, Perkins professor of mathematics at Harvard University, will become professor emeritus at the close of the academic year.

DR. CARL PAAL, director of the laboratory for applied chemistry at Leipzig, and Dr. Fritz Förscher, director of the laboratory for inorganic chemistry in Dresden Technical School, have been elected members of the Leipzig Academy of Science.

PROFESSOR ANDREW BOSS, in charge of the department of farm management of the department of agriculture of the University of Minnesota, has declined an offer to become director of the new government demonstration farms and trial gardens at Mandan, N. D.

PROFESSOR CHARLES PALACHE, of Harvard University, using a fund placed at his disposal by A. F. Holden, '88, has spent six weeks in Maine and New Hampshire collecting minerals for the Mineralogical Museum and the teaching collections.

ASSOCIATE PROFESSOR FREDERICK STARR, of the department of sociology and anthropology in the University of Chicago, has returned from a six months' expedition to Liberia, the purpose of which was to investigate the social and economic conditions of that region. He was accompanied by Mr. Campbell Marvin, a graduate student of the university.

DR. THOMAS L. WATSON, professor of geology in the University of Virginia, addressed the graduate students in geology at Northwestern University, last month, on the "Occurrence and Geology of Rutile, with Special Reference to the Virginia Deposits."

DR. LEWIS SWIFT, formerly director of the Warner Astronomical Observatory at Rochester, and of the Mount Lowe Observatory on Echo Mountain, California, known for his discoveries of comets and nebulae, died at Binghamton, N. Y., on January 5, aged ninety-three years.

MR. HENRY D. MOSENTHAL, a British chemist, known for his work on explosives, died on December 18, aged sixty-two years.

DR. RUDOLF SCHIMMACK, docent for mathematics at Göttingen, has died at the age of thirty-two years.

THE publishing house of Julius Springer, Berlin, announces the publication beginning with the new year of a new weekly journal "Die Naturwissenschaften," which, according to the announcement, "für den deutschen Wissenschaftsbetrieb ungefähr das leisten soll, was die 'Nature' für den englischen und die 'Science' für den amerikanischen leisten." The numbers will contain about 24 pages; the subscription price will be 24 Marks. The *Naturwissenschaftliche Rundschau*, edited by Professor W. Sklarek and published by Friedrich Vieweg und Sohn, which for twenty-seven years has maintained high scientific standards, will be merged in the new journal.

THE number of visitors to the Zoological Gardens, London, for the past year exceeded 1,000,000, the highest on record, and in accordance with the intention of the Zoological Society the millionth person to pass the turnstiles was presented with a free pass to the gardens for 1913.

A MEETING of the executive committee having charge of the arrangements for the British Association meeting in Birmingham next year was held, as we learn from the *London Times*, on December 5. Mr. Howard Heaton, on behalf of the honorary secretaries, presented an outline of the program, which included an average of five engagements each day for eight days, beginning on September 10. In addition to the usual business meetings and scientific discussions, there will be an inaugural address by the President (Sir William White) on Wednesday, a garden party and reception by the Lord Mayor on Thursday, a garden party given by Messrs. Cadbury at Bournville on Friday, excursions to places of interest in neighboring counties on Saturday, special services in the churches on Sunday, an entertainment by the local committee on Monday, and a garden party on Tuesday. For the benefit of the general public

there will be two evening discussions and six popular lectures by eminent scientists during the week. The suggested program was adopted and referred to a sub-committee to be carried out. Sir George Kenrick presented the report of the finance sub-committee, which stated that the amount required to cover the local expenses of the meeting would probably be not less than £6,000. About half that sum had already been promised in response to private appeals by members of the finance sub-committee, and a public appeal would be issued at the beginning of the new year.

THE Melbourne meeting of the Australasian Association for the Advancement of Science, as stated in *Nature*, will be held on January 7-14. The president-elect is Professor T. W. E. David, C.M.G., F.R.S., and the retiring president Professor Orme Masson, F.R.S. The meeting will be held at the university, which is surrounded by large grounds, and can provide ample accommodation. Professor Baldwin Spencer, F.R.S., who is spending the year as chief protector of aborigines in the Northern Territory, will deliver a lecture on some of the results he has obtained. A joint discussion of several sections will be held on the genus *Eucalyptus* and its products. A forest league is being formed in the various states, under the auspices of the association, which it is hoped will rouse public opinion to the necessity of preserving forests, especially round the head waters of the rivers. A large number of committees will present reports, and a full program of papers is expected. The following are the presidents of sections: Astronomy, Mathematics and Physics, Professor H. Carslaw; Chemistry, Professor C. Fawcitt; Subsection Pharmacy, Mr. E. F. Church; Geology and Mineralogy, Mr. W. Howchin; Biology, Professor H. B. Kirk; Geography and History, Hon. Thos. McKenzie; Ethnology and Anthropology, Dr. W. Ramsay-Smith; Social and Statistical Science, Mr. R. M. Johnston; Agriculture, Mr. F. B. Guthrie; Subsection Veterinary Science, Professor Douglas Stewart, Engineering and Architecture, Col. W. L. Vernon; Sanitary Science and Hygiene, Dr. T. H. A. Valentine; Mental Science and

Education, Sir J. Winthrop Hackett. The general secretary for the meeting is Dr. T. S. Hall.

PROFESSOR WALTER N. LACY, of the Anglo-Chinese College at Foochow, China, writes to Professor J. C. Branner, of Stanford University, the following in regard to the work of ants and termites in China. The paper referred to is published in the *Bulletin* of the Geological Society of America, Vol. 21, 449-496.

I have read with much pleasure your paper on the geologic work of ants in tropical America, for which I have to thank you. One or two items from this part of the world, regarding the termites or white ants may be of interest to you, although Foochow is in lat.  $26^{\circ} 58' N.$ —not quite within the tropics.

On pages 478 and 479 you refer to the common ants being enemies of the white ants, and the two not thriving together. A friend of mine in the northwest part of this province has tried successfully placing black ants' nests under the house which was occasionally attacked by the white ants, and found that they were completely rid of the latter, without being in any way inconvenienced by the common ants.

On page 491 you say: "I am not aware that they (the white ants) ever attack living trees." It is not at all uncommon in these parts to find their mason-work passage-ways built up the trunks of growing trees. A few years ago an olive tree near our house was blown over in a typhoon, and it was discovered that the entire tree had been riddled by the white ants; although the tree trunk was from 18 to 24 inches in diameter, little had been left but the outer shell and bark of the tree and the leaves on the branches. For the white ants to do away with trees in this way is not rare, but, as you suggest, their work is not done in a night, but through a considerable period of time, without doubt.

#### UNIVERSITY AND EDUCATIONAL NEWS

GRINNELL COLLEGE received on December 24 a Christmas gift of \$50,000. The money was made immediately available, to be used for any purpose, the donor stipulating but one condition, namely, that his name should never be made public.

MRS. JOHN HALL has given £500 to Sheffield University in memory of her husband. The income will provide each year a gold medal to be awarded to the student who does best in the subject of pathology at the examination for the degree.

The university court of Edinburgh University has given a grant to Professor Whittaker for the equipment of a mathematical laboratory for the practical training of mathematicians and for a research institution. This will, it is said, be the first laboratory of its kind in a British university.

THE general council of the University of Edinburgh has taken action to bring before members of parliament and others interested in higher education the serious danger with which the universities of Scotland are threatened by the recent interference of the treasury with their freedom of internal administration.

CERTAIN citizens of Oberlin recently asked that the part of the endowment funds of Oberlin College invested in stocks and bonds should be listed for taxation. The decision of the auditor of Lorain County has now been rendered in favor of the college, to the effect that according to the laws of the state of Ohio the college endowment funds can not be taxed.

At Harvard University, Dr. Harvey Cushing has been appointed professor of surgery, and Dr. George Gray Sears, clinical professor of medicine. Professor Ralph B. Perry has been promoted to a professorship of philosophy.

W. S. HUNTER, Ph.D. (Chicago), has been appointed instructor in psychology in the University of Texas. F. A. C. Perrin, Ph.D. (Chicago), has been appointed instructor in psychology in the University of Pittsburgh.

MR. CHARLES FULLER BAKER, known for work in various fields of natural science, has entered the faculty of the College of Agriculture of the University of the Philippines as professor of agronomy. In the same college, Mr. A. G. Glodt, formerly of the engineer corps of the French army and a member of the Marchand relief expedition across Africa, is

associate professor of agricultural engineering. Mr. F. C. Gates, who recently finished the work for his doctorate at the University of Michigan, is instructor in botany. Mr. Edgar M. Ledyard, who spent the past year at the University of Michigan where he put the entomological collection in order and left some sixty thousand Philippine insects, has returned to his work as assistant professor in entomology. Dr. H. N. Whitford has resigned as associate professor of forest botany and silviculture, and has returned to the United States.

### DISCUSSION AND CORRESPONDENCE

#### THE VOTE ON THE PRIORITY RULE

TO THE EDITOR OF SCIENCE: A brief rejoinder may be permitted to the report by Messrs. Nutting, Williston and Ward in SCIENCE for December 13, on a vote on the rule of Priority in Nomenclature.

Primarily this vote shows something quite different from what might be inferred from a superficial examination of the report.

It means *not* that the voters have studied the conditions of confusion which the priority rule was instituted to clear up, and which produce the present temporary state of which there has been natural complaint; but that the teachers (of whom the list of voters is exclusively composed) are much annoyed by the uncertainty incident to the period of transition. This is nothing new; everybody has felt it; it requires an almost Roman firmness to give up a familiar if erroneous name; and the wonder is that the vote was not unanimous. Precisely the same state of mind is the cause why we have not yet adopted the metric system, and Russia retains the old style in her calendar.

If the question had been put as to what remedy should be had, other than continuing the work of rectification as rapidly as possible, it is likely there would have been as many minds as there were voters. No teacher likes to give a name to an organism before his classes which he is not certain is up to date. Moreover, some too clever pupil may discover that Jordan, Merriam, Allen, Elliot, Gill, Rich-

mond, and other master systematists reject that name; where then is our infallibility? It is a tearful situation.

However, a complete remedy is at hand which will harmonize all the disputants without sacrificing accuracy or rejecting necessary rules.

It is well known that nearly all the vertebrates have what are called "common" or popular names. These have been carefully preserved by the ornithologists in their check-lists, for example.

Now let the dear old familiar names of each man's particular set of text-books be given the status of "common names," distinguished by (say a plus sign before them) to avoid confounding them with the real names, and have it generally admitted that no odium attaches to the use of a "common name" for our invertebrates, any more than in ornithology, and we have the whole problem solved. Since only one in a million invertebrates has a "common name" at present, no trouble would ensue on that score.

(I expect nothing less than a statue for this discovery, from future generations of teachers.)

#### THE STAINING OF PROTOZOA

TO THE EDITOR OF SCIENCE: Hæmatoxylin is, so to speak, the printer's ink of protozoologists, for this stain is used by all workers in studying the morphology of the cell, and it has come into general use because it tells as much as a single stain can of the essential structures in the architecture of a cell. It is true that various mordants alter, or rather intensify the staining character of certain parts of the nucleus. For example, when "agamous" trophozoites of *Entameba tetragena* are stained by alum hæmatoxylin, iron hæmatoxylin, or phosphotungstic acid hæmatoxylin, or if they are stained with Malory's phosphotungstic acid hæmatoxylin after wet fixation by Merkel's and Zenker's fluids, the different structures in the nucleus—

centriole, karyosome and sub-membranous granules, take the stain in different degrees, yet it is the same chemical basophilic substance that becomes stained.

Hæmatoxylin tells us nothing about the acidophilic substance which seems to play an important part in the physiology of the nucleus.

During the past year, working with *Entamoeba tetragena*, I have been impressed by the lack of information in literature on the subject of the acidophilic substance in the nucleus of protozoa; and in descriptions of protozoa, I have noticed the frequency with which acidophilic substance has been confused with true chromatin (basichromatin). This appears to be due to the use of polychrome stains which have not been thoroughly differentiated, and to the absence of a satisfactory technique for demonstrating acidophilic substance in wet fixed films.

Those who have used the Romonowsky modifications have usually been content with over-toned or blurred pictures. In attempting to identify "*E. histolytica*" in this region and differentiate it from *E. tetragena*, our common pathogenic entamoeba, I have used Romonowsky stains on films which have been so differentiated that excessive amounts of the stain have been washed out as one would differentiate preparations stained with hæmatoxylin. Inasmuch as Romonowsky stains have almost as much tendency to overstain as hæmatoxylin, the necessity for extraction of superfluous stain is manifest.

I have usually selected cover-slip preparations that contained a sufficient number of entamoebæ to warrant further study, and stained both cover-slip and object slide, thereby obtaining three pictures from one film, fresh, hæmatoxylin and polychrome. After staining, the excess of polychrome stain has been removed by means of 95 per cent. ethyl alcohol and ammoniated 60 per cent. alcohol, and I have found that when properly differentiated, the polychrome stain after dry fixation gives a picture entirely different from that of hæmatoxylin after wet fixation. It is different in two respects. It not only shows that there is an acidophilic substance—oxy-

chromatin—within the nucleus quite different from anything yet described for *E. tetragena*, but the remainder and larger portion of the nucleus has a different structure and staining characters from that described from hæmatoxylin preparations of this entamoeba.

The nucleus of *E. tetragena*, when stained with Hasting's stain followed by Giemsa's stain, and carefully differentiated with 60 per cent. ethyl alcohol, to which a few drops of aqua ammoniæ have been added (1 per cent. aqua ammoniæ in 60 per cent. alcohol) is seen to be made up of a clearly defined red substance which takes the form of a ring about the size of the karyosome or smaller. Oftener, it takes the form of a delicate reticulum or of discrete granules lying within the nuclear membrane. This red substance does not correspond in location with true chromatin (basichromatin) which stains with hæmatoxylin, and it should not be confused with basichromatin as some writers have done. The red substance, or oxychromatin, is imbedded in an ill-defined nuclear structure, staining faintly blue which sometimes is made up of slightly refractile achromatic granules of uniform size, imbedded in faintly staining blue substance and surrounded by an achromatic or faintly staining blue ring, corresponding with the nuclear membrane. The cytoplasm stains various shades of blue.

Attention is drawn to this subject with the suggestion that those interested in the cytology of protozoa pay more attention to the acidophilic substance of the nucleus—oxychromatin, for the purpose of learning what part it plays in relation to synchronous changes in the basichromatin of the nucleus and in the physiology of the cell.

It is extremely likely that so clearly defined a substance as the oxychromatin of the nucleus of *E. tetragena* is has an important physiological function, and it would seem that other protozoa might yield interesting and no doubt important information if studied from preparations designed to satisfactorily show basophilic and acidophilic nuclear substance.

SAMUEL T. DARLING

## THE DORSAL SCALE ROWS OF SNAKES

IN these days when so much attention is being given to the variations and minute characters of animals it seems remarkable that such an important trait as the number of dorsal scale rows in the snakes should receive careless treatment. This character is given considerable weight in delineating species and deserves careful attention. From the descriptions one could only conclude that each species has a rather definite number, 17, 19 or 21, as the case may be, and that the variations are abrupt. The facts are far from being as simple as this. As a rule the number of scale rows decreases posteriorly, and there is often a decrease anteriorly, so that the maximum number of rows (the number now given in descriptions) may either extend from the head to beyond the middle of the body, or be restricted to a longer or shorter distance on the middle, sometimes only for the length of two or three scales. Furthermore, the species that exhibit a variation of two or more entire rows on the anterior part of the body also show the intermediate stages in which the extra rows are present on the middle of the body only, which leaves no doubt that the variations in this character are not abrupt but gradual.

From these facts it is evident that the average number of rows characteristic of a species in any region can only be expressed by a formula that gives the number of rows on the different parts of the body. It is not enough to say that a species has a maximum of 21 rows; one should at least know whether the number is 21 for the greater part of the length or only on the middle of the body. Quite evidently a form with an average of 21-19-17 scale rows, which means 21 to beyond the middle and 19 and then 17 posteriorly, is not the same as one in which the scale formula averages 19-21-19-17, any more than one with 21-19-17 rows is the same as one with 19-17 rows, although such variations are thrown together under the present way of recording the rows.

It is a simple matter to count the number of rows on the different parts of the body and this may be conveniently expressed by the

formula given above. At least this much should be done by the herpetologist, if not for the systematist then for the student of geographic variation, for only with this data can one determine the variation in this character and the type in each locality.

ALEXANDER G. RUTHVEN

MUSEUM OF NATURAL HISTORY,  
UNIVERSITY OF MICHIGAN

## THE QUESTION OF TEXT-BOOKS IN COMPOSITION

WHEN a Harvard man thinks of books on English composition he thinks of Professor Wendell, and before him Professor Hill, and before him the dark. Professor Hill's books, though immensely comforting and instructive, ought to be considered as reference books rather than as texts. Therefore, in the winter of 1890-91, when Professor Wendell found himself confronted with the problem of lecturing on composition to a Lowell Institute audience, he looked about him to see what had already been done. He was surprised to find that nothing then in print quite served the turn. All these earlier fellows were too technical and too much absorbed in detail. They laid down hard and fast rules. They had no patience with the growing tendency to say, "It is me." Students could scarcely tolerate their etymology, their prosody, their similes and their metaphors. Professor Wendell felt already, we may assume, something of his present fine impatience with the details of scholarship; he was already, on his academic side, professionally unconventional. Here, then, was a man peculiarly gifted by nature for the work of cleaning house in rhetoric. There resulted the Lowell lectures, and, in time, the "English Composition."

Since then nobody, I believe, has dared to depart from Professor Wendell's ways. We have had composition books written by nearly everybody, for nearly every important institution and academic grade; but none in any essential respect different from the first. Latterly they become more full of illustrative material and exercises. They present examples of faulty and correct writing from

every modern source, beginning with the newspapers and ending with Colonel Bryan and Sarah Orne Jewett. A few have made some additions to the original theory. They undertake to show a logical subdivision of the plans on which paragraphs may be built up. Beyond this there is little difference. The principles of composition, no matter who expounds them, still bear the hall-mark of their origin. They are all dilute and popular. They all present vague, sweeping precepts which relate to criticism, and not at all to the art of writing. These are so abstract that special exercises must be invented to illustrate them, and so lacking in specific helpfulness that any attempt seriously to fix the student's attention upon them quickly kills his desire to write. Between students who find them incomprehensible and those who think them obvious and silly, there is only a small middle class. It consists of those adapted by nature to take orders and obey with mechanical faithfulness.

Some ten years ago these words might properly have been regarded as destructive criticism. At present they can not, for there is little now left to destroy. Few successful teachers of composition now pay much attention to text-book work. Individual conferences with students have partly replaced it. These, however, are now taken for granted, and we no longer write to the papers about them. A newer device, and one even more welcome, because it occupies class-room hours, is "oral composition." Though burdened at the start with the most unattractive name that could have been chosen, "oral composition" has been an enormous success. More than one high-school teacher of English has seen it double the interest in his work. No wonder. It gives the student, what the text-book never furnished, a rational ideal and an intelligible standard by which to judge success.

The principles of English composition, while they lasted, were hardest on us teachers. We, at least, were forced to take them seriously. The burden of illustrating these mechanical rules fell on us. Now a great musician, one

imagines, may go through his five-finger exercises, or what not, and by and by assimilate his technique and perform with the regulated freedom of genius. Whether it can be so with a writer will perhaps never be known. Certainly it can not be proved by us teachers of composition, for none of us was a genius to begin with. We arrive at a state of mechanical perfection in technique, and there we stick. I look back, in my own case, upon the ruin of a promising and individual, though not a solid or brilliant, style. Now-a-days I write with the mechanical regularity of one pumping into a bucket. I have been a faithful disciple of Professor Wendell, and I can now write a paragraph as "theoretically perfect in mass" as anything to be found in the *Nation*. I can write a paragraph explaining what a paragraph should be, and at the same time explaining that the paragraph I am writing illustrates what a paragraph should be; and I can bring both ideas together at the end into the same summary! But suppose me very angry, or very serious about my subject, so much disturbed, in fact, that I was beside myself, and forgot the principles of English composition. Could I then write any paragraph at all? Probably not. No more than a bricklayer could lay a brick without his trowel. Almost the only thing of which I am any longer capable is what Professor Wendell calls "a piece of style."

There should be comfort in the fact that I am not alone. Most of the brotherhood of English teachers is in the same state. If a man has taught composition any time these twenty years, he is marked. You recognize his method as far away as you can read his work. To conclude a paragraph with a summary is for him as unavoidable as to expel breath after inhaling. His style crawls over the page like an inch-worm, constantly measuring its heels up to its chin. I think of these things, and I wish I were upon the hill of Basan, to outroar the horned herd!

The possibility of slighting the text-book work is, of course, entirely agreeable to many teachers of English. They find it in keeping with modern methods in education. School

is let out, there are to be no more tasks, nothing but playing cross-tag with the boys in the yard and developing the "class consciousness." There is among us, as in other subjects, the type of man properly called an "educator." He "draws out" his pupils. Always animated, always with the last word from the *Scientific American* or the *Review of Reviews*, he makes his class-hour a little less interesting than the moving pictures, but more so than a star lecture at the Y. M. C. A. Such a man likes to see bright faces about him. He is accustomed to have his hour looked forward to with pleasure, his classes begging to be allowed to write ten pages, while he sternly holds out for five. His work is "inspirational"; to make it succeed, he must be in the best of physical condition. So he saves himself. He lets his students criticize their own compositions and those of one another. For himself, he resolves to read themes less, and to play golf more. Such a man is merely an accident in an English classroom. If his occupation were adapted to his essence, we should find him preaching on politics and current problems in a modern evangelistic city church. But, as he stands, his students look up to him as a polished gentleman and man of the world. From him they draw culture in the vaguer sense, a dissemination of sweetness and light.

Meanwhile, there is still the teacher. He is to be found in all subjects, even English composition. He hates inexactness and vagueness, he loves to enforce a clear intellectual distinction, he has great confidence in the educational value of abstract thought. On these accounts he is very unhappy, at the moment, in the English class room. The birch was taken away from him long ago, and now they have taken the book. His conference work goes well enough, being confined mostly to punctuation, grammar and the split infinitive; but in the class he finds nothing to do that he considers worth while. His text-book distresses him with its lack of content. How can he hold up his head before his classes as a man of intelligence when he is obliged to spend his hours with them in dis-

cussing principles which would be evident to the child of ten? He was better off in the dark ages, before they made the whole business so simple. Then, at least, there was material for mental exercise.

It is this style of man who does the real work of the schools, that for which parents suppose they are paying. He is less conspicuous than the "educator," for teaching is a curious business. It is the only profession in which men appear to succeed best by neglecting their work and doing other things. At the same time, as it is not now a question of promotion or salary, we may admit that this man of solid, thoughtful mind is the only real teacher. And the question comes up: What are we to do to keep him happy in English composition?

If we assume that no college teacher wants to do his plain duty, and teach spelling and grammar, there are still two other directions in which the outlook for new text-books is more or less hopeful. The first is logic. That subject has been for some time neglected, and now tends to seem a part of "the good old times." College teachers have begun to ask themselves whether they can not introduce some training in logical principles into the English course; though at the outset they are somewhat staggered at the memory of "Barbara, Celarent." Some day there will be a shaking among those dry bones, and then we shall have a text-book for the teacher.

The second direction from which light may come is the artistic treatment of prose. The artistic problem behind the student's theme, if he can be made to see it, will interest him. It will interest also the "educator" and the teacher. If we could find a man among us who is by nature an artist, rather than a critic, he might contrive to tell us how to write. This sort of book is the hardest of all to produce, and the least likely to appear; but, if one could make it, it would be worth as much as all that has yet been written.

A. T. ROBINSON

INSTITUTE OF TECHNOLOGY,

## SCIENTIFIC BOOKS

*Higher Mathematics for Chemical Students.*

By J. R. PARTINGTON. New York, D. Van Nostrand Co. 1912.

A first question is: Do chemists need any higher mathematics? And it must be admitted that the inorganic analytical chemist, the organic synthetic chemist, the agricultural chemist, and a host of others, by a large margin the majority of all, do not need much, if any, mathematics, and perhaps a quarter century ago no chemist was much the better off for a knowledge of the subject. Of late, however, there has been a great development of physical and dynamic chemistry, wherein mathematical methods are of great importance, so that there has come considerable demand for mathematics from a large and growing class of theoretical chemists, and the demand is likely to increase in the future. Indeed if a student desires to read such memoirs as that of Gibbs on the equilibrium of heterogeneous substances, he must have a tolerably thorough foundation in some branches of mathematics.

A second question: Is there any necessity for a special treatment of calculus for chemists? The appearance of such works as Mellor's "Higher Mathematics for Students of Chemistry and Physics" and this work of Partington's would seem to imply that there was. And the publication of special texts for engineers, economists and the like is evidence that others than chemists feel such a need. In this connection we may cite the excellent address by C. Runge at the International Congress of Mathematicians in Cambridge last summer on the university training of the physicist in mathematics. It is there pointed out with force, but kindness, that our mathematicians do not organize their course of instruction with sufficient reference to the advantages of the great majority of their students, namely, those who are going into physics, chemistry, economics, engineering, and, indeed, anything except pure mathematics—and in so organizing them they are not making for any very preponderating advantages for the few students of pure mathematics.

The sort of course in calculus that the elementary student of applied mathematics should have is one where the ideas and methods of differential and integral calculus, including differential equations, are most fully emphasized and thoroughly illustrated by simple formal work applied to a great variety of problems. For it must be remembered that nine tenths of the problems where the student will use his calculus can be treated with the simplest sort of analysis. So long as mathematicians insist upon a training in differentiation and integration which requires the exercise of a considerable amount of advanced algebra and analytical trigonometry, the student of the elementary applications will find himself burdened with unnecessary material which may be hard for him and which can not fail to distract his attention from the work he most needs. And just so long there will be attempts, justifiable attempts, to compile treatises out of the line of the regular mathematical courses for the use of such students.

Whenever a book thus intended for a special class appears it must be judged from a double point of view: First, how is it as mathematics; second, how does it meet the needs of that special class?

Judged from the point of view of the mathematician, Partington's work is far from good; it has that sort of inaccuracy which indicates that its author, no matter how much he may use his mathematics, does not have any thorough knowledge of the subject; it abounds in the kind of glaring crudities with which every serious teacher is familiar on the part of his pupils and which he seeks constantly to eliminate, though often unsuccessfully, from their minds. A few instances must be cited to justify so sweeping a condemnation.

On page 21 in the definition of limit the statement that the variable can never reach its limit is incorporated. With the artificial discontinuous variable of elementary geometry this is true, though unessential; with the continuous variables of physics it is not true. On page 31 in varying the equation  $p v = K$  by assigning increments to the variables the author writes

$$(p + dp)(v - dv) = K.$$

Now  $v - dv$  in place of  $v + dv$  is just the sort of error we have constantly to warn the freshman against. The increment  $dv$  may be negative, but should not be written as  $-dv$ . The author finds the correct result  $dp/dv = -p/v$  incorrectly from an incorrect equation. On page 67 there is this choice bit: "At this point (such as  $P$ ) there is a sudden change of direction; it is therefore called a *point of inflection*." A fine definition! How could the author have made more errors in so short a sentence! On page 86 we find: "It must not be supposed, however, that the series obtained by differentiating a convergent series term by term is also convergent. Thus the series

$$1 + x^1 + x^{1 \cdot 2} + x^{1 \cdot 2 \cdot 3} + x^{1 \cdot 2 \cdot 3 \cdot 4} + \dots$$

is convergent for  $|x| < 1$ , but the series

$$1 + 2x + 6x^2 + \dots,$$

obtained by differentiation, is divergent for all values of  $x$ ." Now if there is any one fact better known or more fundamental than that a power series which converges is differentiable term by term and yields a convergent series, we fail to know what it is. This sort of mistake can arise only when ignorance is blatant enough to talk about matters of which it is so completely ignorant that it does not even recognize its ignorance. No author can wholly avoid errors, but here they are too many and too gross for any charitable inference.

But this book is intended for chemists, and in justice it should be judged chiefly upon what it does for them, what it gives them that they need, what it spares them that for them would be superfluous. Here we must admit that we think the work a great success. To the mathematician, the physicist or the electrical engineer the total omission of all reference to the circular functions and their inverses would seem incomprehensible. But the chemist has no need of oscillating functions; his phenomena run one way. The restraint that the author has exhibited in leaving entirely aside the trigonometric functions is therefore highly commendable. Again, the author uses differentials in differentiating and

gives a tolerably full account of partial differentiation, of the total or exact differential, and of circuit integrals. These matters are of great importance to the chemist. Moreover, though his work is chiefly elementary calculus, it somewhat justifies the more general title *Higher Mathematics* by the introduction of methods of interpolation, extrapolation, approximation formulas and the like, and it finds place on almost every page to appeal to the chemist by selecting exclusively for its applications problems which actually arise in that subject.

The titles of the chapters will give an idea of the scope of the text. Functions and limits, rate of change of a function, differentiation of algebraic functions, maximum and minimum values of a function, exponential and logarithmic functions, partial differentiation, interpolation and extrapolation, the indefinite integral (two chapters), definite integrals, application of the definite integral, differential equations (two chapters), and appendices containing the theory of quadratic equations, the solutions of systems of linear equations by determinants, approximation formulas, and a tabulation of the exponential and natural logarithmic functions. As has been stated, everywhere are found detailed and vital applications to chemistry, to which the list of entries in the index bears ample witness. The student who masters the text will do so with the fullest appreciation of its use to him and will attain a knowledge sufficient for most of his needs, albeit if he wishes to read such highly mathematical works as Gibbs's papers he must pursue his studies somewhat further. For the class for whom it is designed the book is far more useful than the ordinary text on calculus.

EDWIN BIDWELL WILSON

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

*Allgemeine Biologie. Vierte umgearbeitete und erweiterte Auflage.* VON OSCAR HERTWIG. Jena, Gustav Fischer. 1912. Pp. 787, mit 478, teils farbigen, Abbildungen in Text.

The appearance of a fourth edition of this

standard work so soon after the publication of the third (1909) is convincing evidence of its usefulness. Indeed there is no other recent work which deals with such a wealth of material of general biological significance; and there are few biologists who possess Professor Hertwig's facility for clear and forcible presentation. The book is thoroughly readable. Each edition has been an improvement over the preceding, and the present is no exception, through elimination in a few places, but mainly by the addition of entire new sections, and by incorporation of later results in many places throughout. Thus the new matter of the present edition includes the action of  $\beta$  and  $\gamma$  rays on animal and plant tissues, results of tissue culture methods, and the subject of sex-determination. The subjects of chondriosomes, chemotherapy, dimorphism of spermatozoa, heterochromosomes, graft hybrids, hormones, secondary sexual characters and inheritance of acquired characters have been thoroughly revised and brought up to date. These additions and revisions are those noted in the preface, but the revision runs pretty well through the book.

A great merit of the book is that the author, though zoologist, by no means limits himself to animals in the discussion of biological principles, but makes free use of botanical results throughout. His botanical illustrations are often very illuminative, and the constant combination of animal and plant material serves to emphasize the conception of general biology as treatment of the phenomena of life common to animals and plants.

Professor Hertwig still opposes the prevalent view that the problems of biology are fundamentally problems of physics and chemistry. Even if we were to assume, he asserts, that at some remote time the science of chemistry should be so developed as to reveal the structure of all possible albuminous molecules and their derivatives, and that it provided methods by means of which we could ascertain what kinds of albumen and other organic molecules were present in the cell and in what quantities, we should not thereby gain insight into the essence of the living cell and of proto-

plasm. And why? Because the cell is not "living albumen," as has sometimes been said, or a mixture of innumerable albuminous molecules, but an organism composed of determinately arranged vital units, which are again complexes of albuminous molecules and therefore endowed with properties as different from the properties of the simple albumen molecule as the latter from the constituent atoms.

It is perhaps presumptuous, even in so seasoned and honored a veteran as Professor Hertwig, to venture to lay down the limitations of chemical research with reference to biology, and the bounds of the insight that future advance may yield into biological problems, for a reason that will appeal only to those biologists who still use "vital units" in thinking and conceive they know their properties. In any event, such a point of view has its obvious limitations, and they are felt in the treatment of many subjects in the book. On the other hand, this exclusively biological attitude is often of the greatest value in the criticism of premature or narrow generalizations of bio-chemists; and in several places Professor Hertwig's broad outlook on the biological field more than compensates for underestimation of the chemical side.

The treatment of a few subjects still remains rather antiquated. For instance, in the chapter entitled "*Untersuchungen der einzelnen Reizarten*" there is not a single citation more recent than 1891. And in this connection it is surely a serious defect in a work on general biology that the field of animal behavior should be entirely neglected. Another illustration of antiquated treatment occurs in the discussion concerning "*Befruchtungsbedürftigkeit der Zellen*," where the whole discussion, so far as infusoria are concerned, is based on Maupas' work, while the more recent work of Calkins, Woodruff and Jennings, is not even cited. But in most subjects such neglect of recent work is not so obvious, though piety towards pioneers is always observed, as is fitting.

The theoretical foundation of the whole treatment remains as before; if it is sometimes unduly prominent, or even, as it seems to the

reviewer, strained in many places, it nevertheless has an important function in the arrangement of material, and inherent interest of its own as the matured expression of opinion of one of the makers of modern biology; but one can not say that it has promise as a working program; it represents the biological conceptions of the nineteenth rather than of the twentieth century.

The book is full of interest, and may be profitably consulted by working biologists of all grades and laymen alike.

F. R. L.

*Chemical Phenomena in Life.* By FREDERICK CZAPEK, M.D., Ph.D., Professor of Plant Physiology in the University of Prague. New York and London, Harper and Brothers. 1911. Pp. ix+151.

We have before us bearing the above title an extremely interesting and valuable little book included in Harper's "Library of Living Thought." This book should prove to be of great interest to all those interested in the chemistry of life. And I take it that there are no students to-day interested in biology who are not insensibly drawn into the consideration of those varied chemical phenomena so highly characteristic of living things. To the botanist who is familiar with Czapek's "Biochemie der Pflanzen" in the German this little book (really a condensation of that great work) comes with particular interest. It was indeed a most difficult task, as the author admits, when it was attempted to put in condensed and rather *popular* form the subject matter with which he has busied himself for so many years. But it seems that this has been accomplished in a most admirable manner. However, it must not be supposed that this little volume is easy to read and understand; it is far from being adapted to the beginner in biology. The author states in the preface that "a *fair* knowledge of physics and chemistry, both organic and physical, is required, besides the great number of biological facts which must be remembered when we try to obtain a satisfactory survey of the general physiology of the plant." Consequently this

book will be of most value to those who have had a university training which included the above requirements.

With Czapek's well-known contributions to this field of botany all that is necessary to do to portray the value and scope of this book is to indicate the chapter heads as follows: Biology and Chemistry; Protoplasm and Its Chemical Properties; Protoplasm and Colloid-chemistry; the Outer Protoplasmic Membrane and Its Chemical Functions; Chemical Phenomena in Cytoplasm and Nucleus of Living Cells; Chemical Reactions in Living Cells; Velocity of Reactions in Living Cells; Catalysis and the Enzymes; Chemical Actions on Protoplasm and its Counter-actions; Chemical Adaptation and Inheritance.

Certainly every student of botany should have a copy of this book, and should read it again and again, not only for the considerable amount of subject matter here precipitated from a mass of bewildering details, but also because of the broadening of the point of view that is certain to result from its careful study.

RAYMOND J. POOL

THE UNIVERSITY OF NEBRASKA

#### STANDARDIZATION OF THE ACCOUNTS OF LEARNED SOCIETIES

THE United States is now supporting somewhere between 100 and 200 societies of which the object is the extension of learning, the promotion of science and common action in some field of intellectual endeavor. In a country so rich and so generous as the United States, it is not difficult to obtain support for such enterprises, and new ones are added every year. Still many of them find it hard to make both ends meet; a few are able to accumulate a permanent fund.

The accounts of these societies are almost all reported, and in most cases printed, every year; and it might be supposed that institutions founded for the inculcation of truth, exactness and efficiency would give to their supporters a detailed, analytic statement of receipts and expenditures. This is, however, far from being the case. The accounts of the societies are in general brief and far from self-

explanatory. An illustration of the methods of some of the societies, and a test of their thoroughness in keeping accounts is the annual statement for the last year available when this article was prepared, for each of four large and active national societies in kindred fields: namely, The American Academy of Political and Social Science, the American Economic Association, the American Historical Association and the American Political Science Association. Following are the reports of these four societies:

THE AMERICAN ACADEMY OF POLITICAL AND  
SOCIAL SCIENCE

SUMMARY OF INCOME AND EXPENDITURES FOR  
THE YEAR ENDED DECEMBER 31, 1910

The methods of these societies are so different, and the direction of their outgoes so varied, that no comparison is possible without an analysis and restatement of the accounts, as below.

These tables require some explanation: in the first place there is a difference in every case between the number of paying members (found by dividing the annual receipts from members' dues by the annual fee), and the recorded number of members. In societies

gaining rapidly in numbers they will never be the same, but where the difference is so great as appears in the Academy, viz., 945, the presumption is that a lot of paper members are being carried on the rolls.

The cash receipts are a function of two variables, the number of members and the annual fee: the Academy charges \$5 and has

RECEIPTS OF FOUR NATIONAL SOCIETIES  
FISCAL YEAR 1910

<sup>1</sup> Total \$19,270; analyzed into items by guess.

<sup>2</sup> Total \$3,343; analyzed into two items by guess.

nearly twice as many members as any of the other associations. None of the societies apparently makes a practise of soliciting life memberships.

The income from publications also varies, the Academy alone of the four societies having a notable sale for its publications outside its own members. The accounts of that society do not make a distinction between outside subscriptions and the sales of numbers to members of the society.

The Academy and the American Historical Association both have invested funds which add considerably to the income.

The Academy and the Economic Association in the year under review received considerable sums as contributions outright or as guarantees for some special enterprise.

The income of the societies varies from \$3,600 to \$40,000 a year. Those incomes, whatever their derivation or their source, should be considered as trusts to be administered for the benefit of the field of investigation and study represented by the society. All four of

the societies have systems of regular publications which, in order to furnish a basis of comparison, have been calculated according to the number of thousand words. The *Annual Report* of the American Historical Association is printed by the federal government, which much relieves its budget. Each of the societies maintains a periodical—that of the Academy considerably the most voluminous. The Historical Association also publishes a prize essay, which however pays for itself out of sales.

It is difficult to ascertain from the accounts precisely how much these publications cost; but by a careful study and aggregation of items, it appears that the Academy pays \$32.50 per 1,000 words, as against an average of about \$10.50 by the other three associations. The edition of the *Annals* of the academy is larger—perhaps twice as large—as any of the other three societies, but anybody knows that when plates are once made, the expense of running off additional copies is a comparatively small matter. On the other hand, the Academy's cost of publication is relieved by about \$8,000 of receipts. Here again the comparison is confused because the economic and historical periodicals pay contributors. Making allowance for those items it would appear that the net cost per words for the Academy is from two to three times that of the two sister societies.

In all the societies the publication forms one of three principal groups of expenditure. The Academy lumps under the head of "Printing, stationery and postage in connection with publication of *Annals* and with general correspondence, \$19,269.82." It is absolutely impossible from these figures to subdivide between general administration and publication; and therefore \$3,000 is by guess assigned to administration out of the total sum. On the basis of the paying members, the administration per member is about the same, but of course it ought to be distinctly less per capita for the larger society. The same remark applies to the per capita cost for publications: one of the advantages of a large membership is that it should reduce all print-

ing and administration costs. All of the societies maintain some sort of public activity. The Historical Association, and (since the date of this report), the Political Association, have moved in the same direction.

The net expenditure varies from \$30,000 for the Academy to \$4,000 for the Political Science Association. The measure of the effectiveness of these societies is however not the sums spent but the value of the work done. The Academy, with \$30,000 a year to spend, ought certainly to be lending a far greater aid to the problems of the general subject of history, government and economics than the three other societies with their combined income of \$27,000. How far that is the case must be left to the decision of those cognizant of the work of the four societies. One thing is certain, that none of the four societies furnishes a sufficiently detailed account; and that the report of the American Academy of Political and Social Science shows over \$20,000 a year expended for publications as against \$18,000 for the publications of the other three societies. The published accounts do not furnish a basis from which it is possible to find out why its cost per unit for carrying on and printing the publication should be twice as great as those of all the three sister societies doing the same kind of work. Here is an opportunity for a reform in corporate accounts.

### SPECIAL ARTICLES

#### EVIDENCE THAT SODIUM BELONGS TO A RADIOACTIVE SERIES OF ELEMENTS

By the usual test for radioactivity, *i. e.*, the continued ionization of a gas independent of other physical conditions, sodium as an element does not display any activity that is definitely greater than that found in all matter. And the ionizing activity of ordinary matter is so slight that it can not be stated with definiteness whether or not it is of itself radioactive. But radioactivity implies a more fundamental change than that of emitting matter and energy continuously. It implies

an atomic disintegration. If  $\alpha$  particles are emitted the atoms go by leaps and bounds to new atoms of other properties, while if  $\beta$  and  $\gamma$  radiations are emitted the wearing away of the atoms must be just as certain, though no one has been able to conjecture by what steps the change might take place.

Campbell and Wood<sup>1</sup> examined the sodium compounds for ionizing radiations. Their apparatus would have detected an activity much less than that of potassium, which is only one thousandth that of uranium. No radiations could be measured. The fact that a given element does not give out a measurable ionizing radiation is not necessarily evidence that it is not radioactive. For example, we may note the case of radium *D*, which gives no measurable radiations. Yet it disintegrates to half value in about forty years. It is therefore known as a radioactive element. Further, helium as an element may be classed as a radioactive element, providing all helium is of radioactive origin, although of itself no ionizing radiations are emitted. It is sufficient that an element be of radioactive parentage. Thus sodium is a radioactive element if it can be shown that it disintegrates into other forms of matter or if it is the result of the disintegration of other forms of matter.

If sodium is a radioactive element we may at present look for other evidence than direct radiations. We shall inquire if in past geologic time sodium has accumulated radioactivity from other matter, or, on the other hand, if sodium has disappeared or disintegrated into other forms of matter.

#### THE EVIDENCE FROM GEOLOGY

Geophysics furnishes two distinct lines of evidence which favor the hypothesis that sodium belongs to a series of radioactive elements. The first is based on the age of the earth as determined by radioactive data and by the accumulation of sodium in the ocean. The second is based on the relative accumulation in the ocean of sodium compared to chlorine, taken in connection with the relative

<sup>1</sup> *Proc. Camb. Phil. Soc.*, 14, p. 15.

annual output of these two elements by the rivers.

Different authorities give the age to range between seventy and one hundred million years. On the other hand, the data of radio-activity require the age to be about ten times as great as the figures above noted. The principles of the radioactive method are based on the determination of the amounts of helium or lead associated with known quantities of uranium found in rocks of different epochs. The two principal assumptions that are involved are that during the age in question the amount of the uranium and its products which give rise to helium shall have remained constant and that the rate of production of helium shall have remained unchanged. Naturally these two assumptions can not be proved. It can only be said that there is no evidence that casts much suspicion on these. However, in all determinations by the radioactive method some error may accrue owing to a simultaneous deposition of uranium and lead and helium at the time of formation of the rock whose age is in question. As may seem clear later in this discussion, the magnitude of this error is probably not greater than the discrepancy between the age as determined by the accumulation of helium and by the accumulation of lead.

According to experiments by Rutherford and his colleagues one gram of uranium in equilibrium with its products gives  $10.7 \times 10^{-8}$  c.c. of helium per year. Now if we examine the rocks of the different geological epochs we find the rare gas helium enclosed in the rock wherever uranium is found, and further the older the rocks the greater is the amount of the helium associated with each gram of the uranium. Obviously, if we divide the total amount of helium per gram of uranium by the above constant,  $10.7 \times 10^{-8}$ , we obtain the number of years during which the uranium has been depositing helium, *i. e.*, the age of the rock containing the uranium. It may be mentioned that the diminution of the amount of uranium during the age in question is so small that it may be considered negligible in comparison with other errors.

Perhaps the greatest chance for error in the above method of calculation lies in the possible escape of helium from the rock containing the uranium. If so the age of the rock as calculated might be too small. The method would therefore set a minimum limit on the age of the earth.

But if we accept Boltwood's conclusion that the lead associated with uranium in rocks resulted from the radio-active disintegration of the uranium series of elements, and that one gram of uranium gives rise to  $1.88 \times 10^{-11}$  gram of lead per year, we have a check upon the results obtained based on the helium deposits. In general the lead deposits give a somewhat larger age for a given rock than do the helium deposits, which is what we should expect if the helium may escape or if lead might have been deposited with the uranium originally.

Using the method outlined above, Rutherford, in 1906, found the age of a sample of fergusonite to be 240,000,000 years. This was deduced as outlined from the fact that 1.81 c.c. of helium was taken from one gram of the mineral known to contain about 7 per cent. uranium.

Strutt by the same method found two rocks of the Archæan period from Quebec to be 222 and 715 million years old, and two of the same kind from Norway to be 213 and 449 million years old. He also found the average minimum value for hæmatite of the Eocene period to be 31 million years, the same for the carboniferous period limestone to be 150 million, while for the Archæan age the average was 710 million years.

Holmes<sup>2</sup> using as a basis the ratio of the lead to the uranium in the rocks found the values given in the following table:

Period	Age
Carboniferous . . . . .	340,000,000 years.
Devonian . . . . .	370,000,000.
Pre-Carboniferous . .	410,000,000.
Silurian . . . . .	430,000,000.
Pre-Cambrian . . .	1,025,000,000 Sweden.
	1,310,000,000 U. S.
	1,640,000,000 Ceylon.

<sup>2</sup> *Roy. Soc. Proc., Ser. A*, 85, p. 248, 1911.

The above results show that the earth in its present form must be many times a hundred million years old.

However, if we take the evidence as based on the result that is obtained by dividing the total amount of sodium in the ocean by the annual additions of all the rivers of the globe, we find that the age of the ocean can not be more than one hundred million years. Two of the most eminent geologists, F. W. Clarke<sup>3</sup> and J. Joly,<sup>4</sup> think 70,000,000 years to be more nearly the correct age. It seems to me that these estimations were not made without due consideration of the largest sources of error. According to Clarke the saline matter of the ocean if segregated would occupy nearly five million cubic miles, a quantity compared to which all beds of rock salt become insignificant. He also considered the salt of marine origin in sedimentary rocks and he figured that a correction of not more than one per cent. was necessary to allow for sodium disseminated in this way. If there is error due to unequal annual additions by the rivers, Becker<sup>5</sup> argues that it is altogether in favor of making the age of the earth yet smaller rather than larger, perhaps between 50 and 70 million years. There is therefore a discrepancy between the age of the earth as deduced by the two methods. Joly in the *Philosophical Magazine* for September, 1911, favors the view that the radioactive constants are in error, because these constants have not been taken from data extending over a sufficiently long time and under proper circumstances free from doubtful assumptions.

I wish to suggest that there is another explanation of the discrepancy that requires no distrust of the radioactive constants as they have been experimentally determined. In fact, the explanation is merely an extension of our knowledge in radioactivity. The discrepancy may be made to disappear if sodium is supposed to belong to a series of radioactive ele-

ments. If we accept the present data of radioactivity as authoritative, then it must be admitted that there is not enough sodium in the ocean. Perhaps during geologic time elements of higher atomic weight may have been disintegrating into sodium, and therefore the annual output of the rivers now is not the same as the average annual output for all time in the past. That is, the sodium over the land has been increasing by radioactive production while sodium in the ocean has been increasing almost entirely by the annual river supply. This would necessitate that the parent of sodium should commonly exist in relatively insoluble compounds. Otherwise we should have had sodium produced radioactively also in the ocean, and perhaps sodium deposits in the bottom of the ocean. The above fact should give us some clue as to the parentage of sodium, if our whole argument is not faulty. Obviously those elements that have been deposited in the ocean bed in appreciable quantities are eliminated.

The second way for explaining the small sodium content of the ocean is to assume that the sodium in the ocean has disintegrated into other elements. The theory of radioactivity as it now stands, however, requires that the rate of decay of an element shall not be altered by its physical state or surroundings. Then it is highly probable that the sodium in the ocean has not decayed faster than has the sodium on the land, and therefore any diminished quantity of sodium on the ocean would have been offset by a diminished annual addition of the rivers. But the quantity of sodium carried by the rivers is not known to vary greatly with the amount in the earth's crust. It seems then that this second explanation is within the limits of possibility.

The simplest explanation and one which requires no apologies or additional assumptions is based on the supposition that the sodium on the land has been increasing by virtue of the existence of the parent of sodium there and the non-existence of the parent in the ocean or the ocean bed. Perhaps there would be less chance for error if it were stated that the pres-

<sup>3</sup> Bulletin 491, U. S. Geol. Surv.

<sup>5</sup> *Quart. Journ. Sci.*, May, 1909.

ence of sodium must have existed more abundantly on the land. This is along the lines of recent progress, and it is particularly favored because it is the only apparently reasonable explanation for another discrepancy arising from the facts of geochemistry. This additional discrepancy is involved in the succeeding paragraphs.

FURTHER EVIDENCE FROM GEOLOGY INDICATING  
THAT SODIUM BELONGS TO A SERIES OF  
RADIOACTIVE ELEMENTS

There are other elements carried to the ocean by the rivers in a soluble state, which indicate quite a different age of the earth, and consequently favor the radioactivity of sodium. Only those elements that are not deposited in the ocean bed or otherwise removed from the ocean water may be considered for reliable information. Clarke in his "Geochemistry," second edition, p. 125, gives the following facts; the figures in the last column are my own deductions however.

	Annual Out- put from Riv- ers, Metric Tons	Metric Tons in the Ocean	Age of the Ocean
Chlorine ...	$155,350 \times 10^9$	$25,536 \times 10^{12}$	$160 \times 10^6$
Sodium.....	$158,357 \times 10^9$	$14,136 \times 10^{12}$	$89 \times 10^6$

The geologists do not believe that the rivers carried any less chlorine or sodium formerly than they do now. In fact, Becker thinks that they must have carried more previously than they do now. But supposing they did carry less sodium in previous ages (in order to explain away the discrepancies on the age of the earth), there is no obvious reason why they should not also have carried proportionately less chlorine. We may, therefore, for checking purposes, say nothing concerning the annual river output further than it should have varied alike with sodium and chlorine. On this assumption the above figures show that there is not as much sodium in the ocean as there should be. Disregarding the radioactivity data for the uranium series of elements altogether, we see that the above evidence favors radioactivity of sodium. Clarke goes on further to state:

We can understand the accumulation of sodium in the ocean and some of the losses are accounted for, but the great excess of chlorine in sea water is not easily explained. In average sea water sodium is largely in excess of chlorine; in the ocean the opposite is true, and we can not help asking whence the halogen element was derived. Here we enter the field of speculation and the evidence upon which we can base an opinion is scanty indeed.

This excess of chlorine can be accounted for by the same hypothesis that was used to explain the discrepancies in the age of the earth in the early part of the paper, viz., sodium has either accumulated radioactively on the land or disintegrated in the ocean, while for chlorine either these changes have not taken place or else they have gone on at a rate much slower than that in sodium.

From the foregoing, it is obvious that, whether we consider the radioactive data or only the data of geochemistry, either method of approach makes it convenient to assume that sodium belongs to a radioactive series of elements. There has not been to my knowledge any satisfactory explanation for the discrepancies to which attention is called in this paper, either singly or in common. However; it may be noted that the age of the earth as calculated from the chlorine content of the ocean is yet much smaller than that given by the radioactive data, but I do not believe this to be seriously against the argument as presented. It may be that chlorine is accumulating slower than sodium on the land, or perhaps all matter is radioactive in varying degrees, but that is beyond the argument here presented.

It seems worth while to inquire further what elements of atomic weight greater than that of sodium are found more abundantly on land than in the ocean. If our hypothesis is correct we might obtain a list of elements one or more of which should give rise to sodium. And a further study of this list, both in nature and in the laboratory, might reveal the parent of sodium. Of course if the parent of sodium had long ago become extinct this search would be futile.

F. C. BROWN

STATE UNIVERSITY OF IOWA

THE AMERICAN ASSOCIATION FOR THE  
ADVANCEMENT OF SCIENCE  
SECTION A—MATHEMATICS AND  
ASTRONOMY

As both mathematics and astronomy were represented by national societies meeting in affiliation with the association, Section A confined itself to an afternoon session, which was held on Tuesday, December 31. Professor E. B. Van Vleck, of Wisconsin University, presided during this joint meeting of Sections A and B, the American Mathematical Society (including the Chicago Section), the American Physical Society and the Astronomical and Astrophysical Society of America. The meeting was attended by more than two hundred and fifty members of the association and affiliated societies.

In the absence of the retiring vice-president and chairman of Section A, Professor E. B. Frost, director of Yerkes Observatory, his address, entitled "The spectroscopic determination of stellar velocities, considered practically," was read by Professor J. A. Parkhurst. This address will be published in *Popular Astronomy*. The retiring vice-president and chairman of Section B, Professor R. A. Millikan, University of Chicago, presented an address entitled "On unitary theories in physics," which will appear in *SCIENCE*.

In addition to these two addresses the following four papers were presented during the session of Section A:

"Henri Poincaré as a mathematical physicist," Professor A. G. Webster, Clark University.

"Some general aspects of modern geometry," Professor E. J. Wilczynski, University of Chicago.  
"Cosmical magnetic fields," Dr. L. A. Bauer, director of the Department of Terrestrial Magnetism, Carnegie Institution of Washington.

"Preliminary note on an attempt to detect the general magnetic field of the sun," Professor G. E. Hale, director of Mt. Wilson Observatory.

In the absence of Professor Hale his paper was presented by Dr. Bauer. The others were presented by their respective authors. Professor Webster's paper will appear in *SCIENCE*. Brief abstracts of the other three are as follows:

After discussing briefly the general relations between analysis and geometry, Professor Wilczynski considered the notion of a space of  $n$ -dimensions and showed how wide is the applicability of this idea even if we confine our attention to ordinary space, provided a suitable geometric form is chosen as generating element. His devel-

opments culminated in a general theorem which, as he claims, represents a fundamental unifying principle of geometry. This theorem may be stated as follows: The projective geometry of any analytic  $k$ -spread in a space of  $n$ -dimensions is equivalent to the theory of the invariants and covariants of a certain associated completely integrable system of partial differential equations. The paper will appear in the *Bulletin of the American Mathematical Society*.

Dr. Bauer made application of the results of his investigations on the origin of the earth's magnetic field, presented at the Pittsburgh meeting of the Astronomical and Astrophysical Society of America, and Section B of the association at the Cleveland meeting, to the possible magnetic fields of the sun and planetary bodies. A new mathematical method of analysis of the earth's magnetic field was briefly sketched. The paper will appear in *Terrestrial Magnetism and Atmospheric Electricity*, 1913.

Although some definite results have been obtained by Professor Hale, further observations will be required to prove conclusively whether or not the effects found are due to the sun's magnetic field. However, the present observations indicate that the north and south poles of the sun agree in magnetic polarity with those of the earth. As far as the strength of the field is concerned, a knowledge of the Zeeman effect for the lines in question is necessary to determine this. It happens that all of these lines are too faint in the spark to appear on the photographs, but another effort is being made to observe their behavior in the magnetic field.

The investigation is being pushed forward as rapidly as possible, in view of the quiet condition of the sun, since the appearance of sunspots, with their very powerful magnetic fields, will tend to introduce troublesome perturbations. The paper appeared in *Terrestrial Magnetism and Atmospheric Electricity*, Vol. XVII.

The following members of Section A were elected as fellows of the association: S. B. Barret, Harriet W. Bigelow, A. E. Burton, A. E. Douglass, S. Einarson, F. Ellerman, E. A. Fath, J. C. Hamilton, E. S. Haynes, W. A. Hurwitz, E. S. King, C. O. Lampland, F. P. Leavenworth, O. J. Lee, A. O. Leuschner, J. Lipke, C. P. Olivier, G. H. Peters, W. F. Rigge, D. Rines, E. Smith, T. Stephen, H. T. Stetson.

The section elected Dr. J. A. Brashear member of the council, Professor C. J. Fields member of

the sectional committee for five years and Professor T. F. Focke member of the general committee. On recommendation of the sectional committee Professor Frank Schlesinger, director of the Allegheny Observatory, was elected vice-president and chairman of the section, and Professor F. R. Moulton, University of Chicago, was elected secretary for five years.

G. A. MILLER,  
*Secretary of Section A*

### SOCIETIES AND ACADEMIES

#### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

A SPECIAL meeting of the society was held December 3, 1912, at 4:30 P.M., in the New Museum Building, Mr. Stetson, the president, in the chair.

Mr. Wm. H. Babcock read a paper on "The Islands of Antillia," illustrated by lantern slide maps, taking the title of his paper from Peter Martyr's "Decades of the New World," where that author, in view of "the cosmographers," states that he believes these islands were what his contemporary, Columbus, had discovered. Peter Martyr's own sketch map of 1511 was exhibited, showing Florida as one of them under the name of Beimeni: also the maps of Beccaria, Bianco, Pareto and Benincasa, from 1435 to 1482, who may be among "the cosmographers" referred to. They show a group of four large islands roughly corresponding in size, arrangement and other respects with Cuba, Jamaica, Florida or Beimeni and Andros of the Bahamas, and bear on Beccaria's map the names Antillia, Reylla, Salvagio and Insula in Mar (Opposite Island or Island out Before, King Island, Savage Island and Island in the Sea). These are nearly as far west of the Azores as the latter are west of Europe and in such a location must be either the creatures of mere fancy or appurtenances of America. But it is not likely that mere guess-work could produce the remarkable correspondences of these great map islands with the reality, such an island group being altogether unique in the Atlantic.

Behaim's globe of 1492 contains an inscription to the effect that a Spanish vessel visited Antillia in 1414, more vaguely endorsed by another on the map of Ruysch (1508) which credits the Spaniards with finding Antillia long ago. That something of the kind happened in the first quarter of the fifteenth century may be inferred from the fact that Beccaria (1535) names the group collectively "The Newly Reported Islands," most likely borrowing this title legend from his earlier

map of 1426, although the fourteenth-century maps had contained no suggestion of Antillia and her consorts.

The other fifteenth-century maps named corroborate Beccaria, being very consistent in outline and arrangement so far as they go, although two of them give but three islands and Bianco shows only Antillia and a part of Salvagio, which he calls La Man de Satanaxio, but this last seems to be a case of mutilation. However, the Laon globe of 1493 shows only these two main (rectangular) islands.

A current map showed how naturally any craft entering and continuing in the great-sea-current which sweeps from the Azores and the other eastern islands westward to the Antilles would be carried to Cuba and her neighbors.

The Catalan map of 1375 and the Pizigani map of 1367 with its picture of St. Brandan blessing his Fortunate Islands of Porto Santo and Madeira, and the figures of a dragon and a dentapod, each carrying off a seaman from his ship as a warning against westward exploration, were also exhibited. They show the circular island of Brazil west of Ireland and the more southerly crescent-form Man or Brazil, both being important and persistent legendary islands: and the Catalan map in particular shows all the Azores approximately in their real grouping; but neither of them presents anything like the Islands of Antillia.

Dr. Philip Newton read a paper on the Negritoes of the Philippines, estimating their total number (full bloods) at 5,000, though by counting mixed-blood tribes and individuals the estimate is sometimes carried up to 25,000. They are distributed through numerous islands, though not reported from Mindoro. The greater number are on Luzon. There is no difference in them, except as their blood is mingled with that of neighboring races. They are not fishermen, but hunt and gather natural products, using in some districts poisoned arrows, the symptoms of poisoning being like those of strychnine. Their houses are made of upright poles connected by horizontal poles having cross pieces and leaf thatching. They are buried under or near these homes. They rarely bathe and their clothes (which are breech-clouts or aprons) are apparently never washed. Usually these are of cloth obtained in trade, but in some islands, for example Palawan, bark is used. Negritoes do not regularly practise agriculture, but will sometimes plant rice—and perhaps move away before it ripens. A skin disease is the most

prevalent among them, but malaria also prevails. Three incipient cases of tuberculosis were noted. Some other diseases are derived from their neighbors.

W. H. BABCOCK,  
Secretary

#### THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE twelfth regular meeting of the Helminthological Society of Washington was held at Mr. Crawley's residence, November 21, 1912, Mr. Crawley acting as host and chairman.

The secretary presented a paper by Dr. B. H. Ransom entitled "An Important Newly Recognized Parasitic Disease of Sheep." Less than a year ago reports began to come in from inspectors in packing establishments where federal meat inspection is maintained, that a considerable number of sheep were found, on post-mortem inspection, to be infested with tapeworm cysts. These were located in the musculature, and as the infested meat had to be condemned it was a matter of considerable economic importance. German authorities have referred an armed *Cysticercus* in the meat of sheep to *Cysticercus cellulosa* and it was first thought that this was the case here. But the fact that from one to four per cent. of the sheep killed at some establishments were infested indicates that this was not the case, as *Cysticercus cellulosa* is very rare in its normal host, the hog, in this country. Microscopic study showed that the form found in sheep was similar to *Cysticercus cellulosa*, but nevertheless distinct. It seemed further unlikely that the adult tapeworm should be a human tapeworm, as it ought to be reasonably common and to have been recorded before this. The logical host of the adult worm was held to be the dog, and in this connection it may be noted that French investigators of the *Cysticercus* in the meat of sheep have held it to be an aberrant *Cysticercus tenuicollis*, the hooks of the two forms being very similar.

The matter was settled by feeding cysticerci from the meat of sheep to five dogs, and *Cysticercus tenuicollis* to two dogs. All of the dogs developed tapeworms, but those of the five dogs were distinct from those of the two fed *Cysticercus tenuicollis*. Six sheep were then fed tapeworm eggs from the tapeworms of the five dogs, and two were fed eggs of the *Tenia hydatigena* produced in the two dogs from the feedings of *Cysticercus tenuicollis*. One sheep was kept as a check. All sheep fed with eggs from the tapeworms of the five dogs receiving

muscle cysts developed cysts in the muscles, but no *Cysticercus tenuicollis*; both sheep fed eggs of *Tenia hydatigena* developed *Cysticercus tenuicollis*, but no cysts in the muscles. The check sheep and other sheep of the same lot had no cysticerci of any sort.

The new *Cysticercus* is a source of considerable loss to the western sheep man and warrants careful prophylactic measures, such as the destruction of the carcasses of dead sheep and the employment of vermifuge treatment for dogs.

Mr. Foster presented a paper entitled "Some Atypical Forms of the Eggs of *Ascaris lumbricoides*." In examining feces or in dissecting ascarids, certain atypical shapes of ascarid eggs are not uncommonly met with. Some of these eggs are very much longer and narrower than the normal eggs, the length, up to 107 micra, being well outside of the limits given in texts. Sometimes nearly all the eggs in an ascarid will be of this sort. Another atypical form has no trace of the usual external mammillated albuminous covering, although segmentation shows that fertilization has occurred. The third form is the unfertilized egg, the unsegmented central embryonic mass filling the entire shell. A recognition of these forms is important in microscopic examination of feces.

The secretary presented a paper by M. C. Hall and J. T. Muir entitled "A Critical Study of a Case of Myiasis due to *Eristalis*." A five-year-old boy in Colorado Springs, Colo., during the summer of 1912, showed a complex of nervous and digestive disturbances, with emaciation due apparently to excessive vomiting. The case was diagnosed as worm infestation. Immediately after defecation following the administration of a vermifuge, an active larva of *Eristalis* was found in the slop jar. A critical examination of the possibility of myiasis due to "rat-tailed larvæ," and of the circumstances in the case discussed, more especially the prompt recovery of the patient, leads the authors to the conclusion that this is probably a genuine case of myiasis. The evidence is more complete and detailed than in any other published case dealing with myiasis due to these larvæ, the other cases being given in detail in the paper. Additional unpublished cases from the U. S. Bureau of Animal Industry and the U. S. Bureau of Entomology were noted. There appear to have been only seven published cases of myiasis credited to "rat-tailed larvæ."

NEW SERIES  
VOL. XXXVII. No. 942

FRIDAY, JANUARY 17, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

For many years we have carried in our New York house a comprehensive selection of the Scientific Instruments made by the well-known firm of

## CARL ZEISS, OF JENA

which has been duly appreciated by industrial and educational scientists desiring immediate delivery of their requirements, or wishing to inspect an instrument before purchasing.

The most up-to-date models and new lines are promptly added to our stock, to which we invite inspection.

*Literature descriptive of any ZEISS products  
will be gladly sent free upon request.*

MICROSCOPES

REFRACTOMETERS

INTERFEROMETERS

For Gas and Water

HAEMACYTOMETERS

ETC., ETC.

Orders for duty free importation are executed as promptly as possible,

## RECENT PUBLICATIONS OF THE BERNICE PAUAAH BISHOP MUSEUM

### Memoirs, Vol. II, No. 4. Quarto.

The Volcanoes of Kilauea and Mauna Loa on the Island of Hawaii

By WM. T. BRIGHAM, A.M., Sc.D. A compilation of the recorded varying conditions of the volcanoes of Kilauea and Mauna Loa to the year 1909, with index. Paper cover, 230 pages, 28 plates (1 colored), 143 text figures. Price \$3.50, postage 28 cents.

### Memoirs, Vol. III. Quarto.

Ka Hana Kapa: The Making of Bark-Cloth in Hawaii

By WM. T. BRIGHAM, A.M., Sc.D. The story of the manufacture of kapa (tapa) or bark cloth in Polynesia and elsewhere, but especially in the Hawaiian Islands. A very full description of this native manufacture, illustrated extensively from specimens in American and European museums. With a portfolio of full-sized colored lithographic reproductions of tapa. Bound in paper covers, text 276 pages, with 131 figures, index and 50 half tone plates (3 colored). Loose in portfolio, 27 lithographic plates. Price \$12.50, postage, domestic 60 cents, foreign \$1.00.

A list of other publications will be forwarded on request.

## THE CHANGE FROM THE OLD TO THE NEW BOTANY IN THE UNITED STATES<sup>1</sup>

It is generally known that in the seven-  
ties there was a sudden development of the  
study of botany in this country. Just how  
and why this sudden development took  
place at that particular date is, I suspect,  
not clearly recognized, at least by our  
younger men. From histories and reports  
of progress they can learn the main facts,  
but those who, as students or instructors,  
have lived through the transitional period  
when the old botany was changed into the  
new are in a better position to appreciate  
the underlying causes. There are, how-  
ever, few such persons still living and the  
small number is not wholly due to the nor-  
mal death rate. The relative number of  
botanists was smaller then than now and it  
will not do to assume that this was owing  
solely to the lack of attractions in the bot-  
any of the day. The main reason was that  
one could hardly expect to earn a living  
as a botanist. When I graduated from  
college in 1866 and wished to become a  
botanist, Professor Gray told me that I  
ought to study medicine first because the  
possibility of gaining a living by botany  
was so small that one should always have  
a regular profession to fall back upon. In  
fact, at that time medicine was practically  
the gate through which it was necessary  
to pass in order to enter the field of bot-  
any. Some years later De Bary told me  
that, when he was a young man, there was  
a similar state of things in Germany and,  
although desiring to devote himself to bot-

MSS. intended for publication and books, etc., intended for  
review should be sent to Professor J. McKeen Cattell, Garrison-  
on-Hudson, N. Y.

<sup>1</sup> Address of retiring president of the Botanical  
Society of America, given at the Botanists' Dinner,  
Cleveland, January 1, 1913.

any, he had to study medicine, taking his degree in 1853. In 1872, however, things had changed in Europe and when I went to Strassburg to study I was the only student in De Bary's laboratory who had studied medicine. The others had begun the special study of botany on entering the university and were, although no older than I was, much better trained in botany.

In 1866, there were very few botanical professorships in this country, the salaries were very small and the equipment very shabby. Gray was professor at Harvard, D. C. Eaton at Yale and Porter at Lafayette. Torrey, in spite of his distinction as a botanist, really depended on his position as a chemist for his living. The comparatively few positions in government and state stations offered few attractions and changes were frequent. To a young man the prospect was not assuring.

If we look further and ask what was the attitude of the public towards natural science, we find a state of things very difficult to appreciate at the present time. This can be illustrated by my own experience as a school boy. When I was in the high school one of the books we had to study in the upper classes was Paley's "Natural Theology." You may perhaps infer from this that the object was to give us religious instruction. Not at all. The real object was to smuggle a little human anatomy into the schools. This was the way it was done. Very few of you probably ever heard of Paley's "Natural Theology," in its way a remarkable book. In the opening chapter Paley supposes that a man walking in the fields finds a watch on the ground. He sees the complicated machinery adapted to a definite purpose and therefore, according to Paley, at once infers that it must have had an intelligent creator. How much more strongly, therefore, should a contemplation of the organs

of the human body, well adapted to perform special functions, lead us to believe in the existence of an intelligent creator. Paley then proceeds to give a rather mild account of human anatomy illustrated by plates intended to impress the readers; a ghastly head with the cheek dissected to show the parotid gland; an abdomen with the lid removed to show the bonbons inside, the stomach and spleen ingeniously arranged so as to show also the deeper lying organs, etc. Paley's reasoning does not now seem altogether convincing. If you or I had found the watch, we should have seen that it was complicated and we should have known that its purpose was to show the time of day. We should have known also that it had been made by a watchmaker. If, however, a savage who had never seen or heard of a watch had found one in the field, he would have been mystified by the mechanism and would not have had the least idea what its purpose was. Instead of recognizing an intelligent creator he would have regarded the watch itself as a god.

Now, at the time of which I am speaking, it would not have been proper to teach anatomy *as such* in the schools, but anatomy, so far as it served to show the goodness and intelligence of the creator, was quite legitimate. In other words in studying natural history one must never forget that God had made man to be the center of the universe and all other things had been arranged for the benefit of man, and, when facts to the contrary appeared, they must be properly interpreted or denied. Since an omniscient and omnipotent being can not make a mistake, all the species of plants created in the beginning must forever remain as they were created. With this simple theory of living things people were perfectly contented until in 1859 the "Origin of Species" fell like a bomb in

the camp and shattered time-worn theories. That the variations and adaptations of plants and animals were not for the benefit of man, but for the benefit of the plants and animals themselves, was a dreadful heresy. The violence of the controversy caused by Darwin's great work was something of which the present generation can have no conception. It was at its height when I was a college student. Young men were generally inclined to accept Darwin's views, and in our college natural history society most of the meetings were spent in discussing evolution. Some of us had really read the "Origin of Species," but all were ready to talk about it. The older men, even the naturalists by profession, were much more conservative. A few adventurous spirits were more Darwinian than Darwin himself, but college professors had to be careful in what they said, for practically the whole religious world and the greater part of college graduates were not ready then to accept evolution. The bitter feeling of the antidarwinians continued for a considerable number of years, as is shown by the following instance. A little more than twelve years after the appearance of the "Origin of Species" one of our leading universities wished to appoint a professor of zoology. The place was offered to a friend of mine with the stipulation that he should never, directly or indirectly, refer to evolution in his lectures. As my friend was one of the most rabid evolutionists in America, the conditional offer seemed amusing. He, of course, declined and the place was then offered to one hardly less radical in his views, and was again declined. It was rumored that the place was offered to a third person and again declined, but I have no direct knowledge that this was the case. The present incumbent, I presume, believes in evolution, but probably no one

has ever taken the trouble to ask him whether he does or not for, at the present day we should no more think of asking a professor of zoology whether he believes in evolution than whether he is the fortunate owner of a tooth-brush.

At a time when many of the leading zoologists, including Louis Agassiz, were strongly opposed to Darwin's views, the botanist, Asa Gray, exerted a powerful influence in converting the public to the doctrine of evolution. His simple and attractive style enabled him to reach an audience which would have been repelled by the dryness generally supposed to be characteristic of scientific writings. He was also known to be a member of the orthodox church and the good religious people of the country said: if the orthodox Gray sees in evolution nothing inconsistent with revelation, why may we not also accept it? Furthermore, Gray did not go too far in his views, whereas some of the evolutionists started off on a wild sea of speculation whither the public would not be expected to follow.

Having tried as far as the limited time allows to give you an idea of the attitude of the public towards natural science, at the time when I began the study of botany, a word may be said about the botanical instruction in colleges. At Harvard botany was a required study for the whole class during half of the sophomore year. The text-book was Gray's "Structural Botany." Gray had no assistant. To require botany of a whole college class—I am not speaking of agricultural schools—is enough to condemn it to neglect and abuse. This, however, can be said of college students. If their instructors do not interest them they are always able to amuse themselves. In the corner of our lecture room was the trunk of a palmetto which had been used to grace the funeral procession of Calhoun

and afterwards given by Professor Gibbs to Gray as of historical as well as botanical interest. It was the duty of the athletes while the attention of the instructor was diverted to seize the trunk and carry it to the entry and later on to start it rolling down the very winding staircase. This method of studying botany I discovered later was not confined to Harvard. Once while visiting a western university I noticed, to my surprise, a cannon ball back of a door. I asked why it was there and was told, not by a student, but by the instructor himself, that during the lectures the students rolled it along to the head of the staircase when gravity was left to do its perfect work. Afterwards some attention was paid to the lecturer, and how much was learned on any one day depended on how early in the hour the cannon ball was started on its way. Compulsory botany was not a success. In my junior year eight or ten students who really wished to study botany asked Gray to give them some instruction in systematic botany during the season when fresh material could be obtained. The work on our part was entirely voluntary and in addition to our regular work. It was not recognized by the college and we received no credit for it in the rank list. The number of voluntary workers was reduced to two in my senior year, when we had so much regular work as to leave almost no spare time. I have noticed in recent years a growing disposition to demand some reward in the shape of a degree or a certificate of some kind for any work done outside the regular curriculum. To do work for the pleasure of adding to one's knowledge is, I regret to say, getting to be a sign that one is not up to date.

On graduating I followed Gray's advice and entered the medical school, hoping sooner or later to be able to return to botany. The opportunity came in 1870 when

Gray returned from Europe. During his absence Horace Mann, Jr., who had been taking his place, died and I was then appointed assistant. I was always interested in cryptogams and, had it been possible for me to do as I pleased, I should never have studied anything but marine algæ during the rest of my life. It became my duty to arrange the thallophytes of the Gray Herbarium and the work I did was radical, I assure you. Not knowing that Littleton Island was near the North Pole, but supposing it to be somewhere in Long Island, I arranged into the waste-paper basket a number of rather shabby-looking algæ which I afterwards discovered to my mortification were very rare. It did not take long for me to find out that, whatever professors of pedagogy may say, one can not teach a subject without knowing something about it. But where was I to go to study cryptogams? It was proposed that I should study fungi with M. A. Curtis, but he died in 1872. For marine algæ I had to depend on Harvey's "*Nereis*" and J. G. Agardh's "*Species*," works which were not easily followed by a beginner, with occasional reference to the by no means exhilarating "*Micrographic Dictionary*."

Evidently, I must go to Europe, and Germany was the country whose universities offered the greatest facilities for my purpose. The most promising were those of Strassburg, where De Bary was professor, and Wuerzburg, where was Sachs. I chose the former rather at a venture. The other botanists there were Solms and Fr. Schmitz, then a very young man whose work had been in histology. The venerable W. P. Schimper, the bryologist and paleontologist, whose valuable herbarium had been given to the university before the Franco-German war, remained in charge of it and gave a course of lectures. My fellow students were Stahl, Rostafinski,

Gilkinet, Suppanetz, an Austrian, Kamienski, who recently died at Odessa, Karl Lindstedt and Doelbruck, who died young. I learned that I was not the first American who had studied with De Bary. A short time before, while he was professor at Halle, an American, T. D. Biscoe, had taken a course in botany, although not studying botany as a specialty. The only information I have in regard to Mr. Biscoe is that he published a paper on the winter state of our duckweeds in the *American Naturalist* of 1873. There was only one other American, a law student, at Strassburg when I arrived there, for, to the surprise of my fellow-botanists I was not willing to acknowledge as a fellow-countryman a Chilian, whose principal occupation seemed to be duelling and whose English vocabulary was limited to the two words, "damn Yankee."

The general arrangements at Strassburg were the same then as those of other German universities at the present time, but the method of working in the laboratory was very different. I was given a *Chara* to study and in a couple of hours reported that I had studied it. I was told that I had not even begun. Studying, it seems, meant that I must make sections through the scheitel and trace the successive cell-formations. But how was I to make a section and what was a scheitel? The microtome and modern methods of imbedding were then unknown to botanists and all sections had to be made by hand. The nearest approach to imbedding was in sectioning small objects like pollen grains; a few drops of muciage were placed on a cork, the pollen mixed with it and the whole allowed to harden. Then by holding the cork in one hand one could make sections of the pollen if one were lucky. The student of the present day, when hand-sectioning seems almost a lost art, does not

realize what skill in sectioning could be acquired by practise, but, like playing on a musical instrument, constant practise was needed to keep one's hand in. Modern technique, which was borrowed by botanists from the zoologists, has of course many advantages, especially in cytological work, but, for certain work, hand-sectioning has its advantages, as, for instance, the rapidity with which sections can be made.

If I was fortunate in my fellow students at Strassburg, in one respect I was less fortunate. At the time De Bary himself was at work on his "Vergleichende Anatomie," which was published in 1877. Anatomical studies were not his strong point, but, in an unguarded moment, he had promised Hofmeister that he would write the volume for his series and he felt in duty bound to keep his promise. We should have preferred to have had him working on the mycological subjects in which he excelled, but the management of cell cultures and the technique required in such investigations were taught to his pupils. Rostafinski took his doctor's degree while I was in Strassburg, with the thesis, "Versuch eines Systems der Mycetozoen." The monograph of that group did not appear until 1875. I happened to hear De Bary and Schimper talking about Rostafinski's thesis, which they thought was a good work, although they regretted that he had made so many genera. What would they say were they now living, when it almost seems as if we were trying to create a new genus for every species?

In the laboratory I noticed that the students seemed to refer frequently to a book of which I had never seen a copy or even heard. The book was Sachs's "Lehrbuch," second edition, 1870. I bought the book and was perfectly amazed. I had never dreamed that botany covered so large a field. The "Lehrbuch" was an ad-

mirable summary of what was known of all departments of botany up to that date, well written and excellently illustrated. The fourth edition, which appeared while I was in Strassburg, was still better. On looking at the second edition a number of years later, I noticed what seemed to be a curious omission. No mention whatever was made of bacteria. In the fourth edition they are mentioned under *Schizomycetes*. The absence of reference to bacteria in the earlier edition, however, was not an omission. There were no bacteria at that date. There were no bacteria until Cohn published his "Untersuchungen über Bakterien" in 1872. The fact that forty years ago Sachs had never heard of bacteria, while to-day life has almost become a burden, one hears so much about them, is a striking instance of the rapidity of development of a subject having a practical as well as a theoretical value. I know no single book which has had so great an influence in shaping the course of modern botany as Sachs's "Lehrbuch." It may be that the facts there given were generally known in Germany, but they were not known in other countries. On returning home by way of England in 1874, I showed my copy of Sachs to several English botanists and it was evident that it was quite new to them. It was certainly unknown in America. If imitation is the sincerest flattery, the value of Sachs's "Lehrbuch" was quickly recognized, for, using it as a model or basis, there soon appeared a large number of really excellent text-books in various languages in which one recognized Sachs translated, Sachs condensed, Sachs diluted, Sachs trimmed to suit local demands. Publishers, were they capable of gratitude, would have erected a monument to Sachs's memory long ago. Draughtsmen, on the other hand, had little reason to bless his memory. Even now we can

hardly open a new text-book without seeing the inevitable "after Sachs."

One evening I was present at a dinner given by De Bary. On that gay and festive occasion I heard more gossip about botanists than one hears even at a meeting of the Botanical Society of America. My neighbors kept saying: "der schmutzige Kerl." On asking who the dirty fellow was, they said Naegeli. In my innocence I inquired what Naegeli they meant. They answered "Der Naegeli." Even starch could not save his reputation, and they proceeded to tell not one but many tales which I know you are dying to hear but which I am not going to tell you. What I wish to say is this: At the same dinner some one, possibly Rostafinski, spoke of a certain Strasburger, a botanist. I understood him to refer to some botanist living in Strassburg and asked his name. I was told that he was a Pole named Strasburger who lived not in Strassburg but in Jena and had written a work which showed him to be a promising young man. That was the first time that I had heard of Strasburger, who had not then begun his work in cytology. The promise was fulfilled and the young man of 1873 became one of the bright lights of the botanical world. At the close of his long but too brief career he left a brilliant school in a department of botany which he had created and of which he remained until his death the leading spirit. Fortunately we have with us a younger generation admirably qualified to continue the work which he began.

For the last twenty years most young American botanists have thought it necessary to study in Germany to complete their education, but, when I returned in 1874, I was looked upon very much as one would be who had returned from a journey in Thibet or Central Africa. Things had

changed. The country had recovered from the effects of the civil war, money was more abundant and more could be spent on science. New professors were appointed in the colleges and courses for the instruction of school teachers in botany and zoology were provided by private individuals. I have time only to refer to one curious episode in the development of botany in America. I refer to what may be called the biological epidemic which broke out soon after I returned to America and threatened for a time to drive botany from the field. If at some future time some one ventures to write a book on the abuse of the "ologies" the chapter on biology will be the most interesting. As far as I can make out, as originally used, biology did not differ much from physiology. The laboratory manual of Huxley and Martin was planned to correct the common idea that botany and zoology consisted in the description of different species of plants and animals, whereas in reality they are the study of plants and animals in all their relations to one another and to their surroundings. Huxley and Martin's book was extensively used in this country and was in many ways excellent. The criticism might be made that it was not well proportioned. Without saying that it was all lobster, there was so much lobster and so little of plants that there was not enough to make a good lobster salad. Soon it became the habit of young persons who knew precious little about either plants or animals to call themselves biologists, disdaining to be called botanists or zoologists. It does not follow, however, that because one is neither a botanist nor a zoologist one is to be considered a biologist. Trustees of colleges and similar institutions were given to understand that a superior race of beings had arisen, the biologists, and that botanists and zoologists

had had their day. Colleges being always impecunious, this information was gladly received by their governing boards. By calling their zoologists biologists they could escape appointing professors of botany. This clever device for saving a salary worked very well for a few years, but at last it became evident that the teaching by a zoologist with the aid of a text-book, how to distinguish a yeast cell from a fern prothallus and a fern prothallus from a germinating bean, was not all that was wanted in our colleges, although it might have been sufficient in a kindergarten. The epidemic of biology, although it hindered for a time the development of botany in England and America, fortunately never spread to other countries.

Although garrulity is the privilege of old age, I feel that I am still too young to take up more of your time this evening. This occasion, in which the body as well as the soul naturally participates, seemed to me to call not so much for a formal historical account of botany in my day as for a series of personal reminiscences, more or less anecdotal in form, which would throw a little light gained from the experience of one who, although he has lived long, hopes that he has not outlived sympathy with the present, on some of the steps by which our present advanced position among the botanists of the world has been reached. It has been my fortune to see the old order of things overturned by the appearance of the "*Origin of Species*" which, by freeing science from the fetters of a semitheological bias, opened the way to a free scientific study of the distribution of plants and animals and the great questions of heredity and evolution. To most of you this great change is only a historical fact. To me it is a living memory. I, who was almost the first American student to seek the benefit of botanical instruction abroad,

have lived to see the time when a very large number of our botanists have brought back to America the best that Europe had to offer. There was a time when our botany might have been said to bear the mark "made in England." In more recent years it may be said to have been "made in Germany." There are some patriotic souls who hope that the time will come, if it has not already come, when we may say "made in America." I do not share their feeling. To me it seems that botany is destined to become more and more widely diffused until it becomes world-wide and it will be enough if we contribute our proper share to the general stock. I have lived to see the growth of several branches of botany which practically were not studied at all when I was young. Bacteriology and cytology are of recent origin. Plant physiology has been with us a child of slow growth, but it frequently has been the case that the strongest men have been slow in their development. Plant pathology from a crude and semi-popular beginning has become an exact science in whose study and practical application we have already surpassed other nations. When this society meets forty years hence, I shall not be present. Few of you will be present. But whatever of progress the speaker on that occasion may be able to report will be the result of a gradual development. It can hardly be expected that he will have to record any such radical and complete transformation as it has been my privilege to present to you this evening.

W. G. FARLOW

HARVARD UNIVERSITY

#### THE *SIMULIUM*-PELLAGRA PROBLEM IN ILLINOIS, U. S. A.<sup>1</sup>

THE advancement of entomology owes much, of recent years, to the stimulus supplied by

<sup>1</sup>Read at the Second International Congress of Entomologists, Oxford, England, August 8, 1912.

the discoveries made by medical men with respect to the agency of insects in the transmission of contagious diseases; and just now our knowledge of the species, distribution, habits, life histories and ecology of *Simulium* is progressing by leaps and bounds in consequence of the well-known *Simulium* theory of the transmission of pellagra, announced by Dr. Louis W. Sambon in 1905, and fully elaborated by him in the *Journal of Tropical Medicine and Hygiene* in 1910.

This stimulus to a study of these insects reached me, in one of the interior states of North America, in August, 1910, when, in consequence of the appointment by the governor of Illinois of a state commission for the investigation of pellagra as occurring in the insane asylums and other institutions of that state, I was requested, as the official entomologist of Illinois, to contribute to their report an account of the distribution of *Simulium*, especially in the neighborhood of state institutions in which cases of pellagra were occurring. As an investigation of all insects injurious or dangerous to the public health in Illinois is one of the prescribed duties of my office, I was bound to avail myself, to the best of my ability, of this opportune call. This I did by detailing an assistant, Mr. C. A. Hart, August 8, 1910, to commence observations and collections along the central part of the course of the Illinois River, and especially to make a careful survey of the vicinity of the general Hospital for the Insane, built upon a bluffy bank of that stream near the city of Peoria. My reason for giving particular attention to this asylum was the fact that it had been the principal seat of pellagra in Illinois, containing in 1909 eighty per cent. of the cases of this disease—that is, one hundred and twenty-seven out of two hundred and twenty—recognized that year in the whole state. This had preeminence has, in fact, been since maintained, this asylum containing sixty-three per cent. of the four hundred and eight cases known to occur in Illinois during the twenty-six months preceding the first of September, 1911.

In the year 1911 but little could be done on this subject; but beginning with April of the present year a continuous program of observations, collections and breeding-cage studies has been steadily maintained and is still in progress on the Illinois River, and a careful survey has been made of the surroundings of the six insane hospitals of the state, and of the almshouse of the county in which the city of Chicago is situated. Cases of pellagra have occurred in all these institutions during the above-mentioned period, but in widely different ratios to the total number of inmates in each—the Peoria asylum, for example, containing, in 1909, twelve times as many cases per thousand inmates as did any other institution in the state. It thus became a matter of special interest to know the facts in detail concerning the occurrence and abundance of *Simulium* in the immediate neighborhood and in the general vicinity of all these institutions.

Besides this work in the field, the insect collections of my office for many years have been carefully examined, and its field notes and accessions records have been sifted for evidence bearing on the species and distribution of *Simulium* in the state at large; and the whole body of the American literature of the subject has been critically studied, with some reference also to a considerable list of European articles.

According to the present state of our knowledge there are approximately seventy species of *Simulium* on record for the whole world, of which we are known to have but fifteen in the United States of North America. Nine species, or possibly ten—the status of one being uncertain—have been found in Illinois, one of which, *S. hirtipes*, occurs also in Europe. No other European species has been found on the continent of North America, although *S. reptans* is reported from Greenland. The slight attention hitherto paid to these insects in America is illustrated by the fact that two of our nine Illinois species—or three of them, if there are ten in the state—are new to science, descriptions of the two

known to be new being now in press, under the names of *venustoides* and *johannseni*.<sup>2</sup>

As the state of Illinois extends, from north to south, through five and a half degrees of latitude, there is some difference between its most northern and its most southern districts in respect to the predominant species of *Simulium*; but as all have similar habits, and all but one of them are active biters, this fact probably counts for little in the present discussion.

There is some difference also as to the kinds of waters in which the several species prefer to breed, some of them living mainly in the larger rivers, and others occurring only in the smaller streams; but as the state is well watered in all its parts, and is virtually a level plain, there is no part of it which is wholly beyond the reach of some species of *Simulium*. It is true that these insects are rarely seen in some places, and are an annoying nuisance, and indeed a destructive pest in others, especially along the larger rivers in spring; but since we have found them in considerable numbers at a distance of more than five English miles from the nearest water in which they could have bred, and since there is scarcely a small stream anywhere in some part of which *Simulium* larvæ can not be found throughout the spring and summer, even temporary roadside drainage ditches often containing them during the spring season of high water, there must be few people in the state who are not at some time exposed to the attacks of the flies. *Simulium* is, in fact, more completely and uniformly distributed in Illinois than *Anopheles*, and as there is no part of the state wholly and permanently free from malarial disease, there would seem to be no part of it free from danger of pellagra, if this is really transmitted by black-flies.

The contrast is marked between these Illinois conditions and those in Italy, where Sambon and his colleagues studied the problem of pellagra and the distribution of the black-fly.

<sup>2</sup> Since printed in a reprint from the 27th Report of the State Entomologist of Illinois, pp. 32 and 42.

There mountain heights, mountain valleys and level plains make up a diversified topography and hydrography, and the distribution of *Simulium* is similarly diversified. It is one of the main lines of Sambon's argument that the distribution of pellagra is limited by the distribution of *Simulium*, although not co-extensive with it. This test can not be verified in Illinois, however, as *Simulium* is generally distributed. Pellagra, on the other hand, is intensely local, so far as is now known; but to this interesting point I shall presently return.

The life histories of the American species of *Simulium* are very imperfectly known, and the same may be said of those of all other parts of the world as well. No species, in fact, has been carefully followed, in its development, around the year, and on only two of our American black-flies, *venustum* and *pictipes*, has any kind of definite life-history work hitherto been done. Probably studies of this sort are now in progress in other places than Illinois, but if so their results have not yet been made known. In our own state we have gone far enough with this phase of our problem to make sure that six of our species, and possibly all of them, produce two or more generations in a season, and that there is a sufficient variation among the different species in respect to the times at which the successive generations emerge, to make it certain that some *Simulium* species may be producing adults at every time of any average year, from early April to late October. We have, in fact, ourselves collected adults of one or more species, and have bred others, in each of these seven months, but much more frequently in April, May and June, than in any later ones.

The actual number of individuals on the wing, indeed, diminishes rapidly after the main spring outburst, so that it is usually difficult to find an adult *Simulium* in August or September, even in places made almost uninhabitable by them in April and May. This may be due in part to unknown features of the life history of two of the most prolific species, *pecuarum* and *meridionale*, but it is certainly due also, at least in part, to summer

shrinkage of the streams and a consequent reduction in the number of suitable places for the breeding of these discriminating insects. Whatever is the explanation, the fact itself is notorious, and it is of especial interest to our inquiry; for if *Simulium* transmits pellagra, there should be, generally speaking, some seasonal correspondence observable between this highly unequal abundance of the insect carriers of the disease and the number of new cases occurring.

There is, indeed, a very notable seasonal periodicity shown in Illinois in respect to the number of new cases of pellagra, but it is not of the kind anticipated by this reasoning. My attention was first called to the facts last December by Dr. H. Douglas Singer, director of the State Psychopathic Institute, at Kankakee. In the Peoria hospital, where the largest number of our new cases have occurred, statistical data were obtainable from July 1, 1909, to September 1, 1911, and the curve showing the frequency of new cases in this hospital presents five notably high points, each the culmination of a wave of increase, in the period of two years and two months which it represents. In the first of these two waves the twenty-one new cases of July are followed by seventy-one in August, and this maximum by thirty-seven, twenty-three, twelve and three for the months of September, October, November and December, respectively. In January, 1910, there was but one new case; in February and March there were none; in April there was one; and with this a new wave started, reaching thirty-four new cases in June, dropping to but four in July, and rising in a second, lower wave of sixteen and fifteen in August and September, respectively, dropping thence to one in October and none at all until February of the following year.

The largest number of new cases occurring in 1911 was only seven, in August, the next largest number coming in May, when there were six, and the two crests of these waves being separated by the low period of June and July, with one and three cases, respectively. In a word, the two annual high points come in either May or June of two of these years,

and in August of three of them; while in the two years for which our records are virtually complete, the first wave is the highest in 1910, and the second is highest in 1911.

I believed at one time that we might make out a relation of succession between these separate waves of increase and the adult periods of successive generations of *Simulium*, but as my data accumulate this relationship becomes decidedly doubtful; and certainly these double pellagra periods can not be connected with any seasonal differences in the abundance of *Simulium*. If there were any causal relation between these two facts there should be but one high pellagra period to correspond with the single spring outrush of *Simulium* adults; or if there were another it should be much lower than the first.

Sambon reports a periodical character different from this observed in Illinois in the fact that it relates to an increased activity of pellagra—an intensification of its symptoms in individual pellagrins—occurring in spring and in fall, coincident, as he says, in Italy with the time of flight of two generations of the sand-flies; and he uses this fact to support his hypothesis of the dependence of the disease on the insects. Assuming that pellagra is produced by a protozoan parasite, he further assumes that the aggravation of symptoms twice each year is due to a migration to the surface of this hypothetical parasite, which is thus exposed to be taken up by the sand-flies as they draw blood from the skin of pellagrins. The summer and fall recrudescences of the disease he thus connects with the summer and fall abundance of the sand-fly imagoes. His periods are, however, different from ours, the first coming in March or April instead of May and June, and the second in September or October, instead of August as in Illinois. I have not been able to learn from our physicians that any periodicity similar to this described by Sambon has been noticed in Illinois cases, but if it has it would be impossible to correlate it with the facts above described concerning the development of *Simulium* in our state.

There are other interesting points of con-

trast between our Illinois conditions and conclusions and those obtained by a study of the problem in Italy and in other parts of Europe. We are told, for example, that in Italy pellagra is a rural disease, to which town-dwellers are virtually immune, even where there is free communication between the town and adjacent pellagrous districts; but in Illinois we have every year several deaths from pellagra in our largest city, with a population of more than two million souls. Four cases of this disease have lately been reported to me from the private practise of Dr. Oliver S. Ormsby, secretary of the State Pellagra Commission, the sufferers from which had lived continuously in Chicago for years. Pellagra, in fact, can scarcely be said to be with us, as yet, a rural disease, the asylums in which ninety-six per cent. of the known new cases have occurred being in or very near cities and towns, and all cases reported from outside such institutions having come from the town and not from the country. The Peoria asylum, containing sixty-three per cent. of our known pellagrins, is in a suburb of our second largest city. It draws its patients from all parts of the state, but more than a third of them come from Chicago or its immediate neighborhood. Three other asylums, containing thirty per cent. more of our pellagrins, receive between sixty-three and one hundred per cent. of their inmates from Chicago. The closest relations of these especially pellagrous asylums thus seem to be with our largest cities and not with our rural districts. These facts would be more certainly significant, however, if pellagra had been longer known and more thoroughly studied throughout our territory, and if we had complete and reliable statistics from the state at large.

*Simulium* is said in Italy not to live in towns or to enter houses; but in the town of Havana, a village of thirty-six hundred inhabitants situated on the Illinois River near the central part of my state, it is so great a pest in spring that the people screen their windows to protect themselves from the bites of the black-flies; and we have seen these insects collecting there in great numbers on

the inside surfaces of the window-panes of public rooms, such as the offices of hotels. Furthermore, we have found biting species of *Simulium* breeding and emerging in large numbers, not only in the suburbs and outskirts of Chicago, but far within the limits of that great city—in the Chicago River, which traverses the city, passing through its most densely populated districts, and also in drainage ditches beside the streets when these happen to contain streams of running water for a sufficient time in spring. Indeed, it is not too much to say that *Simulium* may breed in any flowing stream within the city where the water is not offensively foul with sewage and other contaminations.

Reasoning from the time of the onset of pellagra in the case of certain infants born in November and in December, when sand-flies are not abroad in Italy, Dr. Sambon comes to the conclusion that the incubation period in these cases could not have exceeded three weeks, this being the interval to elapse between the time when these infants were first carried out in spring to the fields where they might have been bitten, and the date of the appearance of the rash which was the first symptom of the disease. If this reasoning is sound, and these infantile cases are fair examples of the incubation period of pellagra, then I am troubled to explain the occurrence in Illinois of two asylum cases—both reported as first attacks of the disease—one first manifested on the 24th of December, and the other on the 31st of that month, after a period of three or four weeks of severe cold weather. Our latest Illinois collections of *Simulium* adults made in any year were obtained November 5, and these cases consequently seem to have developed some six or seven weeks after any possibility of infection by means of *Simulium* bites. It is possible, however, that this discrepancy is only apparent, and that these were not new cases, arising in the asylum, but recurrent attacks of a disease originating outside and not previously recognized.

*Simulium* does not require, with us, swift-running streams for its development, some of

the species, at least, breeding in any freely flowing water where the surface is broken into a ripple by depending or projecting objects. A stout weed growing from the bottom of a stream near its margin, or a twig bending down and dipping into the water from the shore, or even a trailing grass blade, will in many cases be thickly covered—but only on the up-stream side—with the larvæ first, and afterward with the pupæ, of *Simulium*. We have even found larvæ and pupæ, both in great abundance, coating objects on the bottom of the river at a distance from the shore and at a depth of nine or ten feet—a point in which our observations differ, so far as I know, from any others on record.

In Italy pellagra is said by Sambon to be essentially a disease of mountain valleys, but if this rule applied in America, we should have only imported cases of pellagra in any part of Illinois or, indeed, within hundreds of miles of its borders. There is, in fact, no common topographic feature distinguishing the three principal seats of pellagra in our state. The Peoria asylum, with two hundred and fifty-eight new cases in twenty-six months, is on a bluff about a hundred and fifty feet in height beside one of our largest rivers; the Elgin asylum, with thirty-eight new cases in the same time, is on a more sloping bank, less than half as high, beside a much smaller stream; and the Dunning almshouse is on a level open plain, with no water in its vicinity except a small drainage ditch, which often goes dry in midsummer. The country surrounding all these hospitals is a level or slightly rolling plain, originally covered with prairie grass except where streams were bordered with narrow belts of forest.

From the foregoing it will be seen that, although in this discussion I have been obliged to take a critical attitude towards the *Simulium* theory of this disease, our Illinois data are not, by themselves, conclusive either for or against that hypothesis. This is a source of regret to me, although scarcely a disappointment, as one entomologist, working for so short a time and in so limited an area, could scarcely expect to bring this time-worn

and complicated problem to the point of actual solution; and I must be content with bringing forward my personal contribution of matters of fact to this important inquiry, of a kind to require that they be taken into account in forming an adequate theory of this disease. In the meantime, whether the *Simulium* theory be finally justified or not, it should be especially welcome to us, as I intimated in the beginning, as giving us motive and opportunity greatly to increase our knowledge of these interesting insects; and it is particularly for this reason that I have ventured to bring this imperfect discussion of a problem yet unsolved before this congress of the entomologists of the world.

STEPHEN A. FORBES

UNIVERSITY OF ILLINOIS

#### EOANTHROPUS DAWSONI

A MEMORABLE and crowded meeting of the Geological Society was held in Burlington House, London, on December 18, to hear a paper read "On the Discovery of a Paleolithic Human Skull and Mandible in a Flint-bearing Gravel overlying the Wealden (Hastings Beds) at Piltdown, Fletching (Sussex)," by Charles Dawson, F.S.A., F.G.S., and Arthur Smith Woodward, LL.D., F.R.S., Sec.G.S.

Four years ago Mr. Dawson noticed that a certain road had been recently mended by peculiar flints, which he traced to a shallow pit. A little later he found that the laborers had dug out a "thing like a coco-nut," the fragments of which they threw on a rubbish heap. Mr. Dawson found there a part of a human skull which he showed to Dr. Smith Woodward; they realized the importance of the discovery, but kept it secret until they had time to exhaust the pit. This took a long time, as it is under water for six months in the year. Half of a mandible was found in the undisturbed gravel close to the spot where the skull occurred.

The gravel at Piltdown rests on a plateau 80 feet above the river Ouse and at a distance of less than a mile to the north of the existing stream. Thus denudation to the extent of 80 feet has taken place since the gravel was

formed. In the gravel were found two broken pieces of the molar of a Pliocene type of elephant, a much rolled cusp of a molar of *Mastodon*, besides teeth of *Hippopotamus*, *Castor* and *Equus*, and a fragment of an antler of *Cervus elaphas*; all of which, like the human skull, were well mineralized with oxide of iron. Many water-worn iron-stained flints were obtained which closely resemble the artifacts from the North Downs near Ightham, to which the term "eoliths" is generally applied. A few implements of the characteristic Chellean type also occurred. The gravel is (archeologically) early paleolithic and (geologically) early pleistocene of about the same age as the Norfolk Forest Bed. Professor Sollas places the Chellean industry in the second genial episode of the Ice Age, but the artifacts of Ightham type, and the remains of elephant and mastodon were doubtless derived from an Upper Pliocene deposit.

Although the cranium is very fragmentary, the pieces recovered so abut on one another that an accurate contour of the brain case can be obtained, and a cast could be made of the cavity, which reveals the broad features of the brain. The cranium is typically human, and has a capacity of at least 1,070 c.c. It measures about 190 mm. in length from the glabella to theinion, and 150 mm. in width at the widest part of the parietal region. The bones are remarkably thick, the average thickness being 10 mm. The forehead is prominent and not receding as in the Neanderthal cranium, and the brow ridge is feeble; the occipital bone shows that the tentorium over the cerebellum is on the level of the external occipital protuberance, as in modern man. The temporal muscles extended higher up on the skull than in any recent or fossil man. When viewed from behind it is seen that the cranium is surprisingly broad and low. The mastoid processes are small. There do not appear to be any characters in the cranium which can not be matched severally in various existing human skulls. No facial bones were discovered. The right half of the mandibular ramus is nearly complete to the symphysis and lacks only the articular condyle and the

upper part of the bone in front of the molars. The horizontal ramus is slender, and resembles in shape that of a young chimpanzee (*Anthropopithecus niger*). The lower symphyseal border is produced into a broad flat junction with that of the opposite side, being in this respect completely simian. The ascending ramus is broad, with extensive insertions for the temporal and masseter muscles, and has a very shallow sigmoid notch. Molars 1 and 2 are typically human, though they are somewhat large and narrow; each bears a fifth cusp; their cusps have been worn perfectly flat by mastication. The mandible is certainly the most remarkable feature of the find; although it bears some general resemblance to the Heidelberg jaw, it differs in being less massive, with smaller molars, a still more negative chin, and the simian symphysis. In making a model of the restored jaw Dr. Smith Woodward found he had too much room for the missing teeth and consequently was forced to leave a diastema between the canines and premolars, but on other grounds he believes that the canines were not specially prominent. The jaw as restored is wonderfully like that of a chimpanzee. Thus we have a being with what is virtually a human cranium and a simian jaw. The weakness of the mandible, the slight prominences of the brow-ridges, the small backward extent of the origin of the temporal muscles, and the reduction of the mastoid processes suggest that the specimen belongs to a female individual, and it may be regarded as representing a hitherto unknown species of man for which not only a new species but a new genus must be erected—Dr. Woodward bestowed on it the name of *Eoanthropus Dawsoni*.

Mr. Dawson gave an account of the finding of the specimens, the nature and geographical and geological position of the gravel bed and Dr. Smith Woodward described the remains in a most excellent manner. He pointed out that the skull of *Eoanthropus* was very different from that of *Homo monsteriensis* (*H. neanderthalensis*), and that it bore some resemblance to the skull of a young chimpanzee. He suggested that as the characters of the

adult male chimpanzee's skull diverged considerably from the juvenile characters, so possibly *H. monsteriensis* may have diverged from a type like *Eoanthropus*. Professor G. Elliot Smith was called on to give an account of his investigation on the cast of the cranial cavity, and he pointed out that, while the general shape and size of the brain was human, the arrangement of the meningeal arteries was typically simian, as was a deep notch in the occipital region; he regarded it as the most ape-like human brain of which we have any knowledge. Sir Ray Lankester, Professor A. Keith, Professor Boyd Dawkins, Mr. Clement Reid, Dr. Duckworth, Professor Waterston, Mr. Reginald A. Smith and others discussed the paper.

There can be no doubt that this is a discovery of the greatest importance and will give rise to much discussion. It is the nearest approach we have yet reached to a "missing link," for whatever may be the final verdict as to the systemic position of *Pithecanthropus erectus*, probably few will deny that *Eoanthropus Dawsoni* is almost if not quite as much human as simian. The recent discoveries of human remains in the Dordogne region and elsewhere are demonstrating that several races of man lived in paleolithic times, and we may confidently look forward to new finds which will throw fresh light upon the evolution of man.

A. C. HADDON

#### THE YALE PERUVIAN EXPEDITION OF 1912<sup>1</sup>

ON Thursday, December 19, the Yale members of the Peruvian Expedition of 1912 returned to New Haven. This, the third Yale expedition to Peru, was conducted jointly by the University and the National Geographic Society, the Yale members being Professor Hiram Bingham, '98, director; Professor Herbert E. Gregory, '96, geologist; Dr. George F. Eaton, '94, osteologist, and Mr. Osgood Hardy, 1913, assistant—Mr. A. H. Bustead, the chief

<sup>1</sup>From interviews with members printed in the *Yale Alumni Weekly*.

topographer, and Dr. L. T. Nelson, the surgeon, had returned a couple of days previously, having caught an earlier steamer from Panama. Messrs. K. C. Heald and Robert Stephenson, assistant topographers, will return in the course of a week or so. Mr. Joseph Little, assistant, decided to stay in Peru, having secured a position with the Dupont Powder Company. Mr. Paul Bestor, assistant to the director, had been invalided home two months previously, having suffered from a variety of tropical ailments. Mr. Ellwood C. Erdis, archeological engineer, is coming to New Haven *via* the Berlin Museum, where he proposes to spend some time studying the Peruvian collections there before undertaking the work of putting together the various broken pots that were excavated in the department of Cuzco.

Considerable illness, says Professor Bingham in interviews given since his return, overtook this year's expedition and various members were at times incapacitated. The only serious accident happened to Mr. Heald, who escaped death from falling down the face of a precipice only to rupture the ligaments of his collar bone. Nevertheless he carried out important reconnaissance work for a month after the accident but had finally to be ordered back to Cuzco by the surgeon, so that he was unable to penetrate the jungles of the Pampaconas valley as had been hoped.

The map makers, members of the party say, complain that the seasons are changing in Peru. They expected that the "dry season" would give them plenty of time and opportunity for work, but they found, as did the expedition of 1911, that in the great Peruvian Montaña, the jungles on the east slopes of the Andes, the "dry season" is only a relative term, and is much wetter than the "wet season" in some other parts of the world. They were also hindered by finding that valleys which last year had been noted for their salubrity were now the scene of two violent epidemics, smallpox and typhus fever alternating for the mastery. The prevalence of these virulent diseases also interfered with the plans for the anthropological work. Dr. Nelson, who was

in charge of the anthropometric measurements, neither dared to leave the engineering party as long as they were exposed to fatal diseases, nor cared to expose the party to the dangers of having Indians from infected houses come to camp to get measured. As practically all the houses in the region were infected, a very serious interference for a period of two or three months was the result. Notwithstanding this, however, the surgeon did succeed in measuring nearly 150 Indians, using blanks prepared by Dr. Ferris of the Yale Medical School. Two photographs were taken of each subject, and also a large number of Indians were photographed who would not submit to being measured.

Professor Gregory's work was confined almost entirely to the vicinity of Cuzco and the Huatanay valley. The complex geological problems here presented occupied nearly his entire time in Peru. Results will be given out in a series of articles to be published as soon as possible. Mrs. Gregory accompanied him, and after the illness of one of the assistants was able in large measure to take his place, especially in the development of important photographs.

Dr. Eaton was unusually fortunate in being able to collect and bring home more than fifty cases of osteological and ethnological material which he collected in the vicinity of Cuzco in the ruins of Choquequirau and especially in the ruins of the great city of Machu Picchu. In addition to more than fifty skeletons of the Machu Picchu people who were probably Incas or their immediate predecessors, he found a considerable amount of anthropological material in the burial caves. He also collected a number of bones of prehistoric vertebrates, including mastodon, horse and deer. In addition to his osteological and ethnological work, he had general charge of meteorological observations both on the way down and back and at Machu Picchu.

Arrangements were made with Mr. Burt Collins, the director of the Inca Mining Company, and with Mr. Claude Barber, the manager of the Santa Lucia mine, to undertake the care of four meteorological stations for a

period of five years. These stations will be completely equipped with self-recording instruments, and as they are at widely different altitudes the results should prove to be of considerable value.

The chief work undertaken by the expedition was in connection with the study of the ruins of Machu Picchu discovered by Dr. Bingham in 1911. As has already been stated, Dr. Eaton was in charge of the bone hunting and was fortunate enough to find a large number of caves containing skeletons and ethnological material. The clearing of the jungle and the excavating of the ruins was placed in charge of Mr. Erdis, whose four months at Machu Picchu resulted in about sixty cases of potsherds and pots, and two cases of bronze implements. The making of a large scale map of the ruins was entrusted to Mr. Robert Stephenson, who spent three months at a task which it is hoped will result in the construction of a model of this extremely interesting city. The construction of the model will also be assisted by the more than seven hundred pictures which Professor Bingham has taken of the ruins at different times. In addition to the archeological study of Machu Picchu Professor Bingham also devoted himself to exploring four or five sites of ancient ruins hitherto undescribed, and in a systematic effort to discover the ancient place names and to identify localities in the region occupied by the Incas during the last thirty-five years of their reign.

#### SCIENTIFIC NOTES AND NEWS

THE British New Year's honors include the conferring of knighthood on Dr. Francis Darwin, the distinguished botanist; Dr. R. W. Philip, known for his work for the prevention of tuberculosis, and Mr. Stewart Stockman, chief veterinary officer to the Board of Agriculture.

PROFESSOR EHRLICH, of Franfort, has received the Bavarian Maximilian order for scientific services.

DR. IMBEAUX, of Nancy, has been elected a corresponding member of the Paris Academy of Sciences in the Section of Agriculture.

A TESTIMONIAL is planned to Sir Patrick Manson on the occasion of his retirement in recognition of his work in tropical medicine. The testimonial will be national and international. The national testimonial will consist of a portrait and, it is hoped, a scholarship for the advancement of tropical medicine. The international tribute is to be in the form of a gold medallion.

THE officers of the Geological Society of America for 1913 are as follows:

*President*—Eugene A. Smith.

*Vice-presidents*—James F. Kemp, R. D. Salisbury, C. D. Walcott.

*Secretary*—Edmund Otis Hovey.

*Treasurer*—Wm. Bullock Clark.

*Editor*—J. Stanley Brown.

*Librarian*—H. P. Cushing.

*Councilors*—A. H. Purdue, Heinrich Ries, S. W. Beyer, Arthur Keith, Whitman Cross, Willet G. Miller.

*Chairman of the Cordilleran Section*—J. C. Branner.

*Secretary*—Geo. D. Louderback.

*Councilor*—W. S. Tangier Smith.

At the meeting of the Society of American Bacteriologists, held in New York on December 31 and January 1 and 2 the following officers were elected:

*President*—Professor C.-E. A. Winslow, New York City.

*Vice-president*—Professor Chas. E. Marshall, Massachusetts Agricultural College, Amherst, Mass.

*Secretary-treasurer*—Dr. A. Parker Hitchens, Glenolden, Pa.

*Council*—W. J. MacNeal, L. F. Rettger, D. H. Bergey, H. A. Harding.

*Delegate to Council of American Association for the Advancement of Science*—Professor S. E. Prescott.

At the recent meeting of the American Anthropological Association held in Cleveland, Ohio, the following officers were elected:

*President*—Professor Roland B. Dixon, Harvard University.

*Secretary*—Professor George Grant MacCurdy, Yale University.

*Treasurer*—Mr. B. T. B. Hyde, New York.

*Editor*—Mr. F. W. Hodge, Bureau of American Ethnology.

At the Boston meeting of the American Economic Association Professor David I. Kinley, of the University of Illinois, was elected president for the meeting to be held next year at Minneapolis.

PROFESSOR WILLIAM A. DUNNING, of Columbia University, was elected president of the American Historical Association. The next meeting will be held in Charleston and Columbia, the following meeting at Chicago and a special meeting during the summer of 1915 at San Francisco.

THE Academy of Natural Sciences of Philadelphia has named Dr. Edward J. Nolan, Professor Ulric Dahlgren and H. S. H. The Prince of Monaco as delegates to the Ninth International Congress of Zoology.

LIEUTENANT WILHELM FILCHNER, the German Antarctic explorer, returned with his expedition to Buenos Ayres on January 7 after an absence of fifteen months in the southern seas. He cables from Buenos Ayres that the expedition has been most successful. Lieutenant Filchner purposes continuing his explorations.

DR. WILLIAM CURTIS FARABEE has resigned from Harvard and has accepted a position at the University of Pennsylvania. He will take charge of an expedition to South America, the primary object of which is ethnological study, although scientific men in other departments will accompany the expedition. A steam yacht has been provided and equipped for the comfort and safety of the members of the expedition and for the prosecution of the scientific inquiries for which it is organized. Investigations will be conducted along the Amazon and its tributaries and in the northern part of South America. Provision has been made to keep the expedition in the field for three years.

PROFESSOR ROLLIN D. SALISBURY, head of the department of geography and dean of the Ogden School of Science of the Chicago University, has returned from South America, where he had been investigating the glacial formations of Argentina and Patagonia.

MR. CLINTON DEWITT SMITH is about to return to this country from Brazil. He organized and became president, five years ago, of the first agricultural college in Brazil, intended as a model for other colleges. Professor Smith was for fifteen years director of the Experiment Station of the Michigan Agricultural College.

PROFESSOR M. M. METCALF, head of the department of zoology at Oberlin College, has been granted leave of absence for travel and study during the second semester.

At the annual meeting of the Washington Academy of Sciences, on January 15, Dr. Frederick V. Coville gave the address of the retiring president on the formation of leaf mould.

THE sixth Harvey Society lecture will be given on January 18 at the New York Academy of Medicine by Major Russell, of the United States Army, on "The Prevention of Typhoid."

THE Minnesota local section of the American Chemical Society had recently a special lecture on "The Electron Theory," by Professor W. A. Noyes, director of the chemical laboratories of the University of Illinois.

DR. L. O. HOWARD, chief entomologist of the U. S. Bureau of Entomology, lectured before the undergraduates of Oberlin College on January 7, speaking on certain types of noxious and beneficial insect life. Professor Winterton C. Curtis, of the University of Missouri, lectured there on January 8 on "The Social Value of Abstract Research."

It has been proposed to the municipal authorities of Paris that the memory of Henri Poincaré should be honored where he taught, and it is suggested that the portion of the Rue Vaugirard between the Boulevard St. Michel and the Odéon should be named after him.

A CELEBRATION of the centenary of the birth of James Dwight Dana (1813-1895) was held at Yale University on December 29, in connection with the annual meeting of the Geological Society of America. President Hadley presided and referred in his introductory remarks to Dana's pioneer work in zoology and

geology. Professor William North Rice, of Wesleyan University, read a paper on "Dana the Man"; Dr. E. Otis Hovey, secretary of the Geological Society and curator of geology at the American Museum of Natural History in New York City, spoke on "Dana the Teacher"; Dr. George P. Merrill, head curator of geology of the United States National Museum at Washington, spoke on "Dana the Geologist," and President Fairchild, of the Yale Alumni Association, read the paper on "Dana as a Zoologist," written for the centenary by John Mason Clarke, director of the Science Division of the Department of Education of New York State. Books, pamphlets, monographs, greetings from learned societies and personal memorabilia were exhibited in Chittenden Library during the week.

MR. THOMAS HOWELL, the well-known Oregon botanist, died on December 3, 1912. He was born in Missouri on October 9, 1842, and was a pioneer of Oregon, moving there in 1850. Although he had very scanty schooling, Mr. Howell was far from being an uneducated man. He devoted many years of his life to the study of the flora of Oregon, tramping over nearly every portion of the state. His knowledge of the northwestern flora is embodied in the work entitled "The Flora of Northwestern America." Perhaps the most noteworthy discovery of Mr. Howell was the finding of *Picea Breweriana*, a very local tree and the last of the Pacific Coast conifers to be discovered.

DR. PETER REDFERN, formerly regius professor of anatomy and physiology in Queen's College, Belfast, died on December 22, at the age of ninety-one years.

DR. A. PFARR, professor of hydraulics in the Technical School at Darmstadt, has died at the age of sixty-one years.

THE papers on the program for the Cleveland convocation week meeting were distributed among the sciences as follows:

Mathematics .....	49
Astronomy .....	35
Physics .....	52
Engineering .....	40
Geology .....	27
Zoology .....	84

Entomology .....	73
Botany .....	60
Phytopathology .....	49
Horticulture .....	53
Anthropology .....	27
Psychology .....	56
Biological chemistry and pharmacology .....	63
Anatomy .....	63
Physiology .....	67
Education .....	11
Economics and Sociology .....	13

822

THE department of superintendence of the National Educational Association will meet at Philadelphia from February 24 to March 1. With it meets the National Council of Education, the Department of Normal Schools, the National Society for the Study of Education and a number of other educational societies.

PRESIDENT TAFT in a special message to congress, on January 8, recommended the repeal of the act of congress which prohibited for five years the killing of fur seals on the Pribilof Islands, passed a year ago. Investigation, the president said, showed a remarkable increase in the size of the herd in one season and proved conclusively that only the female seals and the bull male seals need protection, and that thousands of "bachelor" seals can be killed each year without reducing the herd. The act which should be repealed was adopted to give effect to the first seal treaty of 1911 between Great Britain, Japan, Russia and the United States. Although a clause in that treaty, the president points out, seems to give the United States authority to suspend land killing to protect and preserve the herd, if no actual necessity were found for such suspension it was not justified under the convention and the act should be amended.

THE board of managers of the Marine Biological Association's laboratory at Plymouth, England, has recently decided upon a policy of emphasizing the purely scientific and international character of the institution, thus rendering it more readily accessible to American students than it has been in the past. In its equipment it is second only to Naples, being well supplied with apparatus and chemicals required for advanced research, and provided with a steamer of 69 tons burden. An effi-

cient staff of attendants is maintained and every effort is made to meet the special requirements of those who occupy tables, especially when the work is of a physiological or chemical character. Many important papers have emanated from the laboratory during the past three years, and the new policy inaugurated by the board of managers may be expected to render the laboratory the "Naples of the North," and advanced students who contemplate the prosecution of researches upon the marine fauna of northern Europe may advantageously write to the director of the Plymouth Laboratory, Citadel Hill, Plymouth, England, for specific information.

MR. NELS C. NELSON, assistant curator in anthropology at the American Museum of Natural History, has returned from an archeological expedition to the southwest. A systematic search for archeological sites was begun at Ysleta del Sur, a few miles below El Paso, and completed northward to the latitude of Santa Fé. Within this section of the drainage 115 sites of more or less interest were located and about half of these were inspected. Actual excavations were conducted in two localities. First a group of seven large Tanos pueblo ruins, located on the border of the Galisteo Basin twenty-five miles south of Santa Fé, were worked to the extent of determining their age and culture relations; and later one entire Keresan pueblo ruin, located on the Jemez National Forest seven miles northwest of Cochiti, was cleared. Besides digging trial trenches and examining refuse heaps, four kivas and 573 ground-floor rooms were cleared. The debris removed from these rooms ranged in depth from two to twelve feet and represented, with few exceptions, two and three story houses. The resulting collections comprise sixty more or less complete human skeletons and about two thousand artifacts.

DURING the week of January 6 a "Mental Hygiene Exhibit and Conference" was held at Yale University under the joint auspices of the National Committee for Mental Hygiene and the Connecticut Society for Mental Hygiene, assisted by representatives

of Yale University. The public exhibition of the work of the National Committee for Mental Hygiene will later be given in Chicago, Princeton, Baltimore, Boston, and Philadelphia, and is designed to give tangible evidences of the need of public information as to the causes, treatment and prevention of mental disorders. It has already been shown in Washington and New York. Speakers announced to make addresses during the week were: Dr. Henry Smith Williams, of New York City; Dr. Stewart Paton, of Princeton; Dr. George Blumer, dean of the Yale Medical School; Dr. August Hoch, director of the Psychiatric Institute of the New York State Hospitals on Ward's Island, New York City; Dr. George H. Kirby, clinical director, Manhattan State Hospital, New York City; Dr. C. Macfie Campbell, of the Bloomingdale Hospital, New York; Professor William H. Burnham, of Clark University; Dr. Thomas W. Sallmon, New York, and Dr. S. E. Jelliffe, of Fordham College.

THE United States will be the meeting place of the Fourth International Congress on School Hygiene. The preceding congresses have all been held abroad, the first at Nuremberg in 1904, the second at London, 1907, and the third at Paris, 1910. The 1913 congress will be held at Buffalo, N. Y., August 25-30. It is the object of the congress to bring together men and women interested in the health of school children and to assemble a scientific exhibit representative of the most notable achievements in school hygiene. It is believed that the present wide-spread public interest in health education will make the exhibit a particularly attractive feature of the congress. Twenty-five nations have membership on the permanent international committee of the congress and it is expected that all will have delegates at Buffalo. The Secretary of State has officially invited foreign governments to participate. Invitations have also been issued to the various state and municipal authorities, and to educational, scientific, medical and hygienic institutions and organizations. The president of the congress will be Charles W. Eliot, president emeritus of Har-

vard University; the vice-presidents, Dr. William H. Welch, of Johns Hopkins, and Dr. Henry P. Walcott, of the Massachusetts Board of Health. The long list of honorary vice-presidents includes: Dr. Abraham Jacobi, of New York City; Dr. William H. Burnham, of Clark University; Cardinal Gibbons; Dr. P. P. Claxton, United States Commissioner of Education; Surgeon-General Blue, of the Public Health Service; Dr. H. M. Bracken, of the Minnesota State Board of Health; President David Starr Jordan, of Leland Stanford Junior University; Dr. Woods Hutchinson, representing the National Education Association, and many other distinguished physicians, educators and civic experts.

#### UNIVERSITY AND EDUCATIONAL NEWS

MR. JOHN R. STRONG has given to the New York State College of Forestry at Syracuse University for use as a forest experiment station 100 acres of forest land at Tannersville in the Catskills, including a summer residence. The tract will be used as a forest experiment station and for a students' camp in the summer.

WILLIAMS COLLEGE has received \$20,000 from the estate of John Savary, '55, of Washington, D. C. The income from this amount is to be used for the purchase of books for the library.

WESTERN RESERVE UNIVERSITY has received from Mr. Henry F. Lyman, of Cleveland, a large collection of shells, corals and agates. The collection is one begun by Mr. Lyman during a visit to the Hawaiian Islands in 1875.

SCIENCE HALL of Ohio University, Athens, Ohio, has been completed and is now occupied by the three departments of physics, chemistry and biology. The building is a four story structure of red pressed brick, 79 feet by 124 feet, costing about \$120,000. The department of physics and electrical engineering occupies the first two floors. These will provide recitation rooms and offices for the instructors in the department; a large laboratory for general physics, with two dark rooms and appa-

ratus rooms attached; laboratories for the various advanced courses in physics, with the necessary weighing rooms and apparatus rooms; a laboratory for electrical measurements, with apparatus rooms and weighing rooms attached; a dynamo motor and transformer laboratory; a photometric laboratory; a storage battery room; high temperature laboratory; unpacking room; storage rooms; several small research laboratories; constant temperature laboratory; drafting room; shop; private laboratory; library and reading room. The other departments are correspondingly arranged.

A COURSE in general science leading to the degree of bachelor of science is offered for 1913-14 in the College of Arts and Sciences of the University of Vermont. This course is similar to the A.B. and Ph.B. courses in its adherence to the group system, but differs from them in requiring mathematics and physics and a larger amount of work in the scientific group of studies. The course is intended for those who intend to teach the sciences in secondary schools and for those who desire a broad scientific training before entering a technical or professional school. The entrance requirements of the new course lay stress on the sciences rather than on the languages.

THE Massachusetts Institute of Technology will hold a reunion of alumni in New York City on January 17 and 18. There will be special trains from Boston and probably from Washington and Philadelphia. The plans include class luncheons on Friday and a mass meeting in the afternoon; society and fraternity breakfasts on Saturday, departmental luncheons and a banquet in the evening. At the mass meeting on Friday afternoon the following have accepted the invitation to speak: President R. C. Maclaurin, Mr. John R. Freeman, Professor D. R. Dewey, Professor A. A. Noyes and Professor W. T. Sedgwick. Speakers at the department luncheons will include the following:

Course I.—Professor C. M. Spofford, Professor G. F. Swain.

Course II.—Professor E. F. Miller, Professor G. Lanza, Dean Goss, of the University of Illinois.

Courses III. and XII.—Professor R. H. Richards and Professor W. Lindgren.

Course IV.—Professor F. W. Chandler and Professor J. Knox Taylor.

Courses V. and X.—Professor H. P. Talbot and Professor W. H. Walker.

Course VI.—Professor D. C. Jackson, Professor Elihu Thomson, Mr. Gano Dunn.

Courses VII. and XI.—Professor W. T. Sedgwick and Mr. Rudolph Hering.

Courses VIII. and XIV.—Professor C. R. Cross and Professor H. M. Goodwin.

Course IX.—Professor D. R. Dewey and Professor H. G. Pearson.

Course XIII.—Professor C. H. Peabody.

At the banquet on Saturday night President Maclaurin, President A. C. Humphreys, of the Stevens Institute of Technology, and Mr. John V. Bouvier will be among the speakers.

#### DISCUSSION AND CORRESPONDENCE

##### A NATIONAL UNIVERSITY AT WASHINGTON

THROUGH the courtesy of President Charles R. Van Hise, of the University of Wisconsin, the writer is just in receipt of a reprint from *SCIENCE*, of August 16, 1912, entitled "A National University, a National Asset; an Instrumentality for Advanced Research," the same being an address delivered by him at the 1912 meeting of the National Education Association.

The paper is a clear, comprehensive and practical exposition of the desirability and possibility of the fullest practicable systematic utilization, by those having the bachelor's degree with a year's subsequent practical work, of the extraordinary research facilities at Washington, embracing physical science and sociology (the latter including anthropology, political economy, political science and history), with such lectures by government officials as will direct the work to the highest efficiency. As such, the paper is a valuable contribution to the subjects involved, and is so excellent, as far as it goes, that the writer is reluctant to say aught in criticism, and does so only because the cause of education seems to require it.

The paper is not more noteworthy for what it advocates than for what it might be expected to advocate. Its negations are quite as marked as its affirmations. The first paragraph is as follows:

At the outset, the guiding principle may be laid down that at Washington there is no necessity for a university of a type which exists elsewhere, no need of an additional university like the great endowed and state universities of the country. One who advocates a national university at Washington with the idea that it shall be a larger Harvard, Yale, Columbia, Cornell or Chicago, a larger Michigan, Illinois, Wisconsin, Minnesota or California, will fail in his advocacy, because he can not give to Congress a sufficient reason for the expenditure of public funds for another university of a kind of which there is a sufficient number. Not only would such an advocate be met by the above fact, but by the fact that in Germany, where universities are most highly developed, they are state, not national institutions.

In the first place, the statement with respect to Congress is opinion only. In the writer's judgment, sufficient reasons *have* repeatedly been given to Congress, and if Congress has not been appreciative enough of the higher education, the fault has been not with the reasons, but with Congress. The mere fact that Congress has heretofore disregarded the proposals of the most distinguished committee ever constituted in an educational interest (although having a Senate standing committee on the University of the United States which in recent years has made four favorable reports, all but the third unanimous) is no reason for not continuing the campaign until Congress either recognizes the merits of the case or capitulates in the spirit of the unjust judge of Biblical parable.

As for Germany, it needs but be said that, if she has not yet attained the national university conception, she is on the way to it, and the German mind can be trusted to work out the problem of university education to its logical result.

And so the question reverts to the "guiding principle" of the paper. If the writer be not mistaken, there were Wisconsin colleges, excellent for their day, already existing when the

University of Wisconsin was inaugurated. What need, or "necessity," to use the word in the paper, was there for the institution over which President Van Hise is proud to preside? If Michigan, Indiana, Illinois, Iowa and Minnesota had state universities, and Wisconsin had none, would he not, as a resident of Wisconsin and an educator, not only advocate a state university for Wisconsin, but also wish it made as broad and strong as possible—if practicable, "larger" than the others? Indeed, would he deprecate the establishment of a first-class state university wherever there is none to-day? It is not likely. Then why discriminate against the District of Columbia, the nation's ground, and deny it the high privilege of an institution of the "university type," commensurate with the ideals, needs and resources of the nation?

He has faith in the "university type" of education in the states. He considers it there a very valuable and noble agency. But when he enters the District of Columbia his faith leaves him. What is the matter? Is not the nation but a larger state? Is the genius of the nation unsuited to the conduct of the fullest instrumentalities of education? Is the national atmosphere unsuited to that form of institution, the "university type," which both the reason and the experience of mankind in all ages have proven the most fit for the development of the higher learning, and which has served its purpose elsewhere so admirably? Apparently so. For, when he leaves Madison as an educator, he arrives at Washington chiefly as a scientist. What has transformed—contracted him? Has the spirit of the broadest learning, fostered in his northern home, become enervated by his removal to a more southern clime? Has the materialistic and commercial spirit of the age, which he withstood so nobly in Wisconsin, gained the ascendancy on the banks of the Potomac? Has he lost that priceless gift of the mind—vision? Whatever be the reason, his educational view has narrowed, and in the capital of his country, where, if anywhere, it might be expected to be comprehensive, it is principally limited to the sciences. Swedenborg,

to be sure, saw that science, with all its uses, is but the husk of knowledge. But Swedenborg would be laughed out of a modern court of science. Science (unfortunately) has little use for seers. And so, for some unexplained reason, it is illegitimate, or unwise, or unsafe, or inappropriate, or impracticable, to do at Washington, in the name and with the support of the nation, what it is eminently legitimate, and wise, and safe, and appropriate, and practicable to do, to a less extent, at Madison, for instance, in the name and with the support of the state of Wisconsin.

Is President Van Hise any more a citizen of Wisconsin than a citizen of the United States? Does his ambition for American education halt at state lines? Would he have pride in no institution of the "university type" beyond the state and privately endowed universities? Are not these institutions, however great and strong, constantly seeking enlargement, and likely to continue to do so indefinitely? And yet do not they themselves recognize the significant fact that, with every increase of knowledge, the domain of the unknown, so far from decreasing, only expands to the view? If the first love of these institutions be for learning, why should not they welcome any new institution of the "university type," whether less or "larger" than themselves, calculated to assist in the search for truth—and welcome it the more in proportion to its power and importance? Is it possible that they imagine themselves, with their ever necessary limitations, the only institutions of the "university type" needed for the exploration of the boundless fields of knowledge? Can he be satisfied with them, or they with themselves, when a greater institution of the "university type" than any of them can ever hope to become may be created by the nation as a co-worker and helpmeet in the domain of universal learning? Can institutions of the "university type" be too numerous, or any one of them too "large" to realize the sublime conception of Johann Kepler, "the legislator of the heavens," when he exclaimed: "O God, I think thy thoughts after Thee!" Will President Van Hise

mention a single argument, valid for a state university, that will not be at least equally valid for a national institution of the "university type"?

The state and privately endowed universities have done a noble educational work, and are contributing much to the advancement of American civilization. And it is no fault of theirs that they can not perform a nation's educational service. It is no disparagement of them that a national institution of the "university type" can do what they, either individually or collectively, will never be able to accomplish. It is the function of nationality to effect more than what is possible to lesser entities, and in no field of service can the national power confer a more signal benefit upon humanity than in the cultivation of the highest and broadest learning. In so far as a nation fails in this regard, it is especially recreant to its trust. And the educator can do his country no finer service than in persuading the nation to be true to itself by providing, in its own great name, the fullest instrumentalities for the pursuit of knowledge universal. Nor can these agencies be furnished in any form so well as by the establishment at the national capital of an institution of the time-tested "university type"—an institution analogous to the eloquent Charles Sumner's "grand temple of universal peace, whose dome shall be as lofty as the firmament of heaven, as broad and comprehensive as the earth itself"—such a university as was in the prophetic vision of the writer's recently deceased father, Ex-Governor John W. Hoyt, for the last nineteen years of his life chairman of the National Committee of Four Hundred to promote the establishment of the University of the United States, when he wrote:

a broad and noble institution, where the love of all knowledge, and of knowledge as knowledge, shall be fostered and developed; where all the departments of learning shall be equally honored, and the relations of each to every other shall be understood and taught; where the students devoted to each and all branches of learning, whether science, language, literature or philosophy, or to any combinations of these constituting the numer-

ous professional courses of instruction, shall intermingle and enjoy friendly relations as peers of the same realm; where the professors, chosen as in France and Germany, after trial, from among the ablest and best scholars of the world, possessed of absolute freedom of conscience and of speech, and honored and rewarded more nearly in proportion to merit, shall be, not teachers of the known merely, but also earnest searchers after the unknown, and capable, by their own genius, enthusiasm and moral power, of infusing their own lofty ambition into the minds of all who may wait upon their instruction; a university not barely complying with the demands of the age, but one that shall create, develop and satisfy new and unheard of demands and aspirations; that shall have power to fashion the nation and mold the age unto its own grander ideal, and which, through every change and every real advance of the world, shall still be at the front, driving back from their fastnesses the powers of darkness, opening up new continents of truth to the grand army of progress, and so leading the nation forward and helping to elevate the whole human race.

But President Van Hise apparently does not wish any such institution as that. He would have the state or privately endowed universities—necessarily the less competent agencies—attempt the broader educational labors, and leave the narrower work to the nation—inherently the more capable instrumentality. The greater field is too high and "large" for the nation. Some of the organic constituents of the nation, with other scattered agencies, can perform the national educational function better than can the nation itself. With all respect to the distinguished gentleman, the writer is impelled to ask, Could provincialism go further? His university attitude at Washington is what might be anticipated of a scientist, but is it what would be expected of an educator?

And so, why should *not* the nation establish, maintain and develop, in its name and at its capital, an institution of the "university type," calculated to become eventually the leading university of the world? The essential reason for such an institution, as has been shown, is, not that it may be "larger" than some other, but that, it being supported by the nation, the cause of learning and of truth will

be more fully served than will otherwise be possible. And this reason is not only legitimate. It is controlling. The claims of these high interests are paramount, and no lesser institutions or interests can properly be allowed intervention at the bar of American education.

A word on a subsidiary matter—degrees. The paper would deny to the national institution it advocates the power to confer them. Now, the writer assumes that President Van Hise desires for his proposed institution every agency that will contribute to its attractive force and its standing in the learned world. But will he say that degrees will not contribute powerfully to these important ends? Have not degrees in all ages been proven stimulants to study, certificates of attainments, and passports to practical opportunities in after life? Would not an institution lacking authorization to confer them be necessarily handicapped and lowered in the estimation of other institutions and hence its usefulness and honor be diminished? He of course appreciates the value of degrees both to students and to institutions, but he would confine them to the state and privately endowed universities. He says:

After a student has continued his work at Washington to the point where he would have a doctorate, he may take his examination and qualify himself for his doctorate at the institution at which he previously studied, and thus add to the prestige of that institution. Naturally, a part of such qualification would be a thesis prepared by using the material in the bureaus and departments.

A remarkable proposal—quite as surprising an anomaly as the paper's "guiding principle"! What would President Van Hise say if a student, after completing an undergraduate course at the University of Michigan, for instance, should take a graduate course at the University of Wisconsin, and then return to the University of Michigan for his examination, thesis and doctorate? Is it too much to say that the president of the University of Wisconsin would make a vigorous protest? And rightly. The laborer is worthy of his hire. Honor to whom honor is due. Fortu-

nately, the spirit of equity among American universities would not permit such an infringement of university rights. But what he would resent for his state he proposes for the nation. He would give his state her dues, but in the case of the nation he would add insult to injury and put it off with a defrauded as well as a fragmentary institution. How will the spirit of equity among our institutions of learning meet such a real proposal as this?

Would a degree lose its value because conferred by a national institution? Indeed, would not its value be thereby indefinitely enhanced? And at the same time, would not the very fact that other institutions of the country were made the necessary gateways to the national institution operate to augment and strengthen those other institutions? If degrees are desirable for the University of Wisconsin or for Harvard, by what process of reasoning are they found undesirable for the national institution proposed in the paper? Is there more concern for the prestige of the state and privately endowed universities than for the prestige of the national institution?

Had the paper not laid stress on the "prestige" of the state and privately endowed universities of the country, the writer would say no more on that subject, for the word, as used, involves more than one unacquainted with the history of the national university movement would imagine. "Prestige," and its offspring, pride! There is pride, and there is pride, and they differ as darkness from light. There is pride which concerns individuals, as such, and which is loath to see any "larger" excellence than that rendered possible by its own circumstances. And there is pride with an eye single to the content of that which another is better circumstanced to accomplish, and individuals, as such, are forgotten in the greater good. Which form of pride shall characterize American education?

The paper is candid enough to admit that such an institution as it advocates would not properly be called a "university" at all. It says:

If there be prejudice against calling the institution above described a national university, it

may be given some other name, since as a matter of fact the institution proposed would be different from any existing university in that it would not profess to give a complete system of courses regarding any subject, but would give such specialized courses as the facilities at Washington made advantageous; and also it differs from a university in the respect that it would not grant degrees.

The university title for such an institution would indeed be a misnomer and hence misleading and indefensible. The present writer, as is evident, has in view for his country a true national university. By the term "university," undergraduate as well as graduate work is generally understood, inasmuch as most of the work done in institutions bearing that title always has been, is, and ever will be undergraduate. As a matter of fact, however, the national university advocacy, almost from Washington's day to this, has been for an institution that would not be a rival to any others—for an exclusively graduate university—an institution that shall stimulate, elevate, standardize, coordinate and supplement American public education, utilize the government facilities, conduct government researches and investigate the unknown; inspire ambition for the highest learning, maintain cooperative relations with other institutions and increase their patronage by making its honors the goal of their graduates; foster nationalism, provide the educational facilities which Americans seek abroad, and, by attracting foreign students, diffuse democratic ideas—an institution that will, to an extent possible to none other, whether one or all, advance the cause of learning and give the United States a new and supreme dignity and influence.

The people of the District of Columbia are, indeed, entitled to an undergraduate as well as graduate institution of learning, and one of the former grade could be affiliated with the latter. But the District is a very small fraction of the United States. The supreme need is for learning and for the nation, for the highest and broadest institution possible of the "university type" at Washington—a need to be measured both by what the institution can do for learning and for the nation, and

by what the nation can do for the institution—a need which, so far from decreasing with the growth of other institutions, increases with the years, as the nation becomes greater and as the infinity of truth is ever more fully realized.

There are offences of omission as well as of commission. It is bad enough to offend at all against one's country. But the paper under consideration, in presuming to set bounds to educational opportunities under the national name and auspices, and in the fullest and most fruitful form yet evolved—an institution of the "university type"—commits a yet graver offence—an offence against learning. No man and no set of men can afford even half-disloyalty to that sacred cause. The instrumentalities for the pursuit of knowledge may be circumscribed only to the ultimate disappointment of those audacious enough to attempt the curtailment of its beneficence. The temple of universal learning has no forbidden shrines or prohibited forms of worship, whether for an individual, a state, or a nation, and they who would pronounce any interdict there must reckon with the everlasting law of progress.

(Since the above was written, the writer has received a letter from President Van Hise, in answer to one remonstrating against the apparent lacks in the *SCIENCE* paper. President Van Hise says:

In response to your letter regarding a national university, I have to say that I advocated the ideas presented in my paper with the belief that the steps there suggested should be the first ones. As a matter of practical expediency, it seems to me to be wise at the present time only to push for those ideas regarding a national university of which there is some chance of acceptance. If the steps I advocate were made at first, it is my conviction that the future would take care of itself. With a national university once founded, its growth would take place wherever sooner or later it appeared such growth would be advantageous to the nation.

If President Van Hise intends the institution he advocates as the beginning of a real national university, the author is gratified, but the paper gives no hint of such intention, with

respect either to its scope or its degree-conferring power—its constitution, in a word, as an institution of the “university type”—and, while it may be necessary to begin as he suggests, the writer deems it important to keep the ideal before the country, and so lets the paper stand as written.)

KEPLER HOYT

4114 FESSENDEN PLACE,

#### NEO-VITALISM AND THE LOGIC OF SCIENCE

TO THE EDITOR OF SCIENCE: In the discussion to which you have recently given space concerning the availability for science of the system of implications to which vitalism and the conception of entelechies lead, it is important to refresh one's memory concerning the general methodological postulates of science, for in the final analysis every special argument in such a case is nothing but the assertion of a specific point of view in regard to the system of conceptions with which science works in reducing the world of phenomena to order.

The conception of intelligible order is the product of a slow intellectual development which is reenacted by every human society in its progress toward civilization and by every child in its growth toward mental adulthood. Between the theoretical limits of a world of anomy and the assumption of necessary law the evolution of this concept presents an infinite series of modifications. The universal presence of law is the underlying assumption on which all investigation proceeds, and the advancement of science is measured by the field which it has redeemed from chaos and conceived in terms of intelligible order. But in certain of its relations this conception is scarcely more than a theoretical postulate which expresses a logical conviction as to the nature of the world and inspires the persistent search after new laws. It expresses the belief, in regard to each unreduced phenomenon, that the logical canons which have guided investigation to a triumphant conclusion in other fields must ultimately be found valid here also.

As to the phenomenal basis of such concep-

tions common observation sufficiently establishes the fact of recurrence, both of elements and complexes. Familiarity with these connections of experiences, however, does not carry the mind inevitably toward their uniformity. Man's first uncritical reflection leads only to the general expectation of recurrence. Failures and fulfillment must equally be accepted as facts. In one field order prevails, in another, caprice. It is an empirical inference which no more assumes necessary connection as its reflective postulate in the one case than it does anomy in the other. But the human mind is not content to rest at this stage. The world of phenomena is not a pure object of contemplation. It is endowed with energy and penetrated with living potencies and purposes, conceived in terms of agents and active causes. These spiritual powers in whom change is grounded are unique as well as individual, and each is marked by a characteristic activity. The world must be taken as it is found; if unpredictable as well as dependable successions occur, the causes to which they are referred must correspondingly vary. Arbitrary and capricious wills appear on the theater of events along with those which are consistent and inalterable. Wonder and miracle lie embedded in the world's structure alongside of established and predictable order.

The habit of thus conceiving phenomena in terms of disparate principles dies hard. It yields only before the slow extension of law as the investigations of science are pushed farther and farther and one range of phenomena after another is brought under control. At first it is not perceived by the scientist himself that the postulate of universal and necessary law underlies all his procedure, that the conception of uniformity is not confirmed by the slow accumulation of evidence but constitutes the basis of every conclusion he draws. The principle of all scientific method is established only when this relation is first clearly apprehended. As the connections of phenomena are more widely discerned the region of anomy undergoes progressive limitation and the world of miracle gives

place to a universe of law. Order replaces disorder, necessity supplants chance in the thoughts of men, until the realm of experience is finally viewed as a consistent and rational whole, wherein every change is conditioned by uniform antecedents and expressible in terms of natural law.

The application of this point of view, it may logically be said, implies a preliminary treatment in which phenomena are organized in a unitary system of classifications on the basis of specific resemblances and differences. But the process of defining and naming, of conceiving individuals in terms of fixed characteristics and referring each to its place in a logical scheme may be said merely to provide the data for the mind's final operation whose field is the interaction of things. The world is treated dynamically as well as statically. The subject of specific characteristics is also the origin of certain effects. It has its place in a causal series as well as in a classificatory system. The logical relations of likeness and difference must be supplemented by the empirical relations of genesis and historical origin. To connect events in this way is to explain them. The world as a system of objects can only be described; to be explained it must be conceived as a system of orderly successions in time. The universal principle of explanatory science is thus to be found in what is termed the conception of causal relation, since it is simply the generalization of this idea of uniformity in historical succession. Natural science therefore rests finally upon the assumption of mechanism and excludes all other conceptions.

Historically the explanations of science have been supplemented at every stage by principles dependent upon the assumption of purpose or function, but every such recourse represents a failure in the scientific undertaking or a loss of the scientist's vision. Its interpolation indicates either the presence of an unresolved problem or a confusion as to the nature of scientific explanation. The ideal of science is, from the methodological point of view, perfectly clear; it is to determine the atomic constitution of the world and

to formulate the mechanics of its changes. The particular constitution of the units and formulas with which the scientist works may vary from age to age, since these are necessarily provisional and relative to the level of analysis attained at any given time; but the formal ideal of all analysis is unaffected by such changes and remains theoretically constant. The unit must be simple, the formula universal. No ultimate difference among the constitutive units, and no partition of the world between irreducible forms of change can be admitted. This is the fundamental assumption from which the scientist can not allow himself to be swerved by any complication of the phenomena to be treated or any difficulty in their resolution.

Such a postulate can be maintained only in view of the fact that science is not an attempt to exhaust the account of reality, and that its presuppositions constitute but a necessary methodological delimitation. Reality is viewed by man in a series of differing relations, each of which involves a specific set of such presuppositions. With none of these other points of view, however, can science have even contact; and the penetration of his own field by the conceptions to which they give rise can mean only the disorganization of his results.

The traditional form in which this adulteration of scientific method has been manifested is an employment of the conception of creative spirits, essences and powers as explanatory formulae. Angels and demons, entelechies and souls, function and purpose, force and will; vitalistic, morbidic and soporific agencies have been invoked in turn as explanatory hypotheses. It may be that human reflection has need of this whole class of conceptions in its complete review of reality; but in the special work which science in general undertakes they can afford no help whatever. Each relapse into such modes of thought marks the point at which scientific analysis has stopped and amounts to nothing more than the confused recognition of an irreducible element in experience. This the scientist must recognize as well as any other, but it is absurd to make

of it a constitutive or explanatory principle. It affords no means of analysis; it determines no specific change; it contributes no formula of relation. At whatever level it appears this conception stands only for the unresolved residuum by which reflection is faced.

Thus in the study of organic life it may be that the biologist is unable to state the facts of development in terms of the known chemistry of the cells, or of the local relation of parts in the segmented ovum and their polarities and bilateralities, or of the influence of external agents upon the organisms; but it is nevertheless inadmissible to formulate the problem in terms of a conception which falls without this whole system of principles and to say that, since the chemical and mechanical conceptions which we are now able to apply to organic development have proved inadequate to the statement of that process in its entirety, we must conceive it as autonomous and treat it in terms of entelechies. Autonomousness is a conception which falls without the domain of science altogether, because it applies to the thing only in its self-dependent totality—with which philosophy deals—and not to the thing in its relations to other things, as science must conceive it. Only in terms of their interaction can the empirical reason explain things at all; and in the case of organic development, as of all other processes, explanation must be through the determination of specific causal relations.

This mechanistic conception of science is of course a purely methodological assumption into which no ontological meaning is to be read. Its nature is misunderstood when, for example, it is called materialistic. The mechanistic conception applies to all facts which fall within the domain of science, whatever the metaphysical interpretation which may be given to them.

#### A PROTEST

TO THE EDITOR OF SCIENCE: Permit me to offer an emphatic protest against the closing

paragraph of Dr. Dorsey's letter in this week's SCIENCE (December 6). It is Dr. Dorsey's right, if conscience and judgment impel him, to express disapproval of missionaries in respect to either their purpose or methods or both, but to accuse them of "distortions," made from mercenary motives, is an utterly unjustifiable bit of spite. It not only reveals lamentable ignorance of facts, but betrays that intolerant and biased attitude of mind against which scientific men are supposed to particularly guard, and which in my judgment vitiates Dr. Dorsey's whole argument.

HUBERT LYMAN CLARK

#### QUOTATIONS

##### THE EFFICIENCY NOSTRUM AT HARVARD

THERE has been a great deal of groping in the dark over the problem of raising the quality of our universities and colleges. But light has appeared at last. There will no longer be any futile casting about for improvements here and changes there, no more mere scratching of the surface. Somebody at Harvard has gone straight to the heart of the matter. Indeed, he has solved the whole problem in point of principle, though of course the details of the beneficent revolution he has started remain to be worked out. What has been needed all along has been some simple and yet profound guiding principle, and this is what the new move at Harvard supplies. See that you get your money's worth out of each professor—this is the philosopher's stone, which, firmly and steadily applied, is going to transmute into gold all the baser metal of our university faculties.

Seldom has a great reform been ushered in so noiselessly. "Harvard professors and instructors," so goes a newspaper account, "are thoughtfully rubbing troubled brows to-day while they ponder over an intricate network of blanks and spaces whereon Assistant Controller Taylor has requested them to record the exact disposition which they make of all time spent in the interests of the university." The assistant controller states that he desires these data for the purpose of using them "as

a basis for pro-rating salaries to the various classified functions"; but, after supplying a formidable array of blanks to be filled with this end in view, he winds up with a request for information concerning "Contributory Activities," the giving of which is optional. These include the number of hours spent on "research work carried on personally by the instructor," and certain other things which, like this, "are of a quasi-private nature." The assistant controller recognizes that the variations in such data due to the personal equation "would make impracticable the direct use of these figures for the purpose of distributing salaries," but nevertheless he is apparently of the opinion that they would be a comfortable thing to have, and so he asks for them. And quite right, too; for the optional of to-day may be the compulsory of to-morrow, and it is well to "get a line" on these professor people, even if you can't pin them down to exact facts and figures.

In sober truth, this news from Harvard is a very serious matter. It touches the very vitals of the professor's calling. It ought to bring out from the Harvard faculty, and especially from the men of light and leading in that faculty, an impressive protest; and the most impressive form the protest could take would be that of a dignified but firm refusal to comply with the demand made upon them. For what is at stake at Harvard is nothing less than the whole character and status of the American professorate. To be a university professor has hitherto meant, in this country, as in all the world, to give to the university yourself—your personality, your talent, your capacity to interest, to instruct, to inspire. Many professors have, to be sure, fallen woefully short of fulfilling this ideal; many have been deficient in ability, many in character. But the one great thing that has made the calling attractive to the best who are in it has been that this was the plane on which it was understood to rest. It offers none of the glittering material rewards of other vocations; it seldom holds forth the allurements of fame. In this country, its dignity has been far below that which belongs to it in Europe, thanks to an exaltation of the

idea of management and administration elsewhere unknown; but the recognition of the personal nature of the professor's work, of a distinctively personal measurement of his value, has never been abandoned. It is Agassiz, or Child, or Martin, or Gibbs, or Norton, or Gildersleeve—not so many hours of their labor—that Harvard, or Yale, or Johns Hopkins has had the good fortune to possess; and every faithful and competent professor has a right to feel that the same is true of him in his degree. But how long would that feeling survive under a system which required each professor to make report of every hour that he spent upon his work, and have his pay doled out to him accordingly?

It is easy to accuse those who object to the introduction of this efficiency nostrum of being reactionaries—upholders of the doctrine that whatever is is right. But it is still easier to reply to the accusation. Not because our universities and colleges are all that they ought to be, but because the proposed remedy is a crude and barbarous one, do we reject that remedy. We ought to have more competent teachers, we ought to have more inspiring leaders of research; but we shall not get them by means of time checks or card catalogues. The American professor is already far more subject to managerial control than his fellow in Germany or France; but it is in America, and not in Germany or France, that the cry of incompetent professors and inefficient instruction is continually heard. What is needed, above all things else, is to make the professorship attractive to superior men—men of originality, men of power, men of enthusiasm. When you have got all your time-card and efficiency-measure mechanism going, you may be able to compel every professor to come up to a certain standard; but you can not compel the men whom you ought to have as professors to enter the calling. You may get the same amount of "results" out of the faculties for less money, or a greater amount for the same money, so far as "results" can be measured by your mechanical methods; but what you have lost you will never be able to measure. And what shall it profit the uni-

versity to have gained countless student-hours and experiment-units and to have lost what is highest and best in it?

\* \* \* \* \*

President Lowell has sent to the members of the Harvard faculty a statement which amounts to something like a repudiation of the preposterous circular of inquiry issued several days ago in the name of the assistant controller of the university. A more complete repudiation would have been more welcome, but it should be safe to assume that Dr. Lowell's statement that "answers were intended to be wholly voluntary" and that "the recent circular was issued under a misunderstanding" means the end of this folly. The episode is one that Harvard should be glad to forget, except in so far as it drew out—as it did, though we are not informed as to what extent—threats of resignation on the part of men who had a proper conception of the professor's calling. It is humiliating to think that such a protest should have been made necessary at our country's most distinguished seat of learning; but as it has happened, we trust that the feeling of self-respecting professors has been made so manifest as to preclude the possibility of any resurrection of the foolish scheme.—New York *Evening Post*.

#### SCIENTIFIC BOOKS

*Methods in Chemical Analysis Originated or Developed in the Kent Chemical Laboratory of Yale University.* Compiled by FRANK AUSTIN GOOCH, Professor of Chemistry and Director of the Kent Chemical Laboratory in Yale University. 1912. New York, John Wiley & Sons; London, Chapman & Hall, Ltd. Pp. xii + 536. Price \$4 net.

In his prefatory note the author states that "the object of this volume is to present the principal results reached by workers in the Kent Chemical Laboratory of Yale University in the investigation and development of methods in chemical analysis." As a rule, only those procedures are included which have been definitely proven to be useful, and the experimental data given are those immediately related to the facts stated. Copious refer-

ences to original papers render further information regarding details, discussions and variations of procedure easily accessible if library facilities are available.

The subject matter is divided into twelve chapters, the first of which deals with "Appliances and General Procedure," the second with "The Alkali Metals," the third with the copper group, and so on, following the groups in the order of increasing valence across the periodic table.

The book is in no sense a text-book, nor is it of the character of a work for general reference with respect to methods of chemical analysis. It is, rather, a bringing together of abstracts of papers, all emanating from this laboratory so well and widely known for its contributions to chemical literature in this important field, but published in many journals throughout a long series of years. As such, it is a most remarkable compilation and can not fail to be of service to those in search of reliable analytical procedures, although its usefulness will be more like that of a "Beilstein" than that of a "Fresenius."

If it is recalled that the material is presented in concise, abstract form and yet occupies more than five hundred pages, it will be evident that the volume constitutes a striking tribute to the versatility and activity of Professor Gooch and his associates and a record which it would be exceedingly difficult for any other laboratory to parallel. The compilation is that of one who is a master in the art of clear, accurate and concise statement, but the compiler has characteristically repressed the evidences of his own share in the many investigations which made this volume possible. It is a book which should do much to uphold the "dignity of analytical chemistry," so warmly defended by the late Dr. C. B. Dudley, and one which may well incite others to renewed endeavor in this fundamental field of chemical science—a field which some have, of late, tended to regard as of inferior importance, but which happily shows signs of again asserting its claims to a fair share of recognition.

H. P. TALBOT

*Introduction to the Rarer Elements.* By PHILIP E. BROWNING. Third edition, thoroughly revised. New York, John Wiley & Sons. 1912. Pp. xii + 232.

Our knowledge of the rarer elements has been considerably extended since 1908, when the second edition of "Browning" appeared.

While the general scheme of the work remains the same as in the two previous editions, the author has made many changes and additions throughout: for instance, the chapter on qualitative separation has been extended by including new analytical diagrams, working directions, and notes; the chapter on technical applications has been much improved by the addition of considerable material; and a table of spectroscopic lines and plates illustrating typical spectra have been added. The revision has been quite thoroughly done. For the first time the work has been well indexed; this improvement in itself greatly enhances the usefulness of the book.

Among the omissions may be noted the following: The test for the platinum metals (except osmium and ruthenium) devised by Curtman and Rothberg (this is the most delicate chemical test for platinum); and the conduct of the platinum metals toward various gases (Phillips, *Am. Phil. Soc.*, March 17, 1893).

It would be advisable in later editions to give the original references to the literature on technical applications, especially to the patents; and to include a complete bibliography of the treatises on the rarer elements, if any bibliography is given.

CHARLES BASKERVILLE

*Light, Photometry and Illumination.* A thoroughly revised edition of "Electrical Illuminating Engineering." By WILLIAM EDWARD BARROWS, JR., B.S., E.E., Professor of Electrical Engineering, University of Maine. New York, McGraw-Hill Book Company. 1912. Pp. ix + 335.

Some of the science, and most of the art, of illumination is still in a decidedly unsettled state, and he who wishes to write a text-book

on the subject has a narrow course to sail between the Scylla of obsolescent matter and the Charybdis of controversial discussion. Professor Barrows apparently has more fear of the first danger; at any rate, he has in several parts of his new text gone perilously near to the second. A considerable part of the book is made up of quotations and passages adapted from recent papers. As a résumé of important articles of the last few years the work is useful, and its value is augmented by the care which has been taken to give references to the original authorities. By copious use of quotations the author to some extent disarms criticism and shifts responsibility to the original authors, but for purposes of instruction the book would be more valuable if some of the lengthy quotations were replaced by a digested presentation of the problems to be met and the facts supposed to be established.

The treatment of radiation which serves as an introduction to the book is characterized by a looseness of expression which can not fail to produce hazy ideas in the mind of the student. As examples may be mentioned the statement that "at wave-lengths greater than those of red light the energy radiated is in the form of heat" (p. 1), and the naïve criticism of the bolometer because it "is apt to indicate the heat rays rather than the luminous rays" (p. 93).

Even more serious are certain misstatements of fact, *e. g.*, "since the radiation varies as the fourth power of the temperature, it is evident that the greatest efficiency of radiation will be obtained at the highest temperatures," and "it follows from the above that the efficiency of the source as an illuminant will vary greatly with the temperature" (p. 4). These statements precede any mention of the real cause of the increase in efficiency, that is, the shifting of the radiation toward shorter wave-lengths with rise of temperature.

The discussion of the Luminous Equivalent of Radiation in Chapter III. is anything but clear. Its vagueness is due in part to the promiscuous use of terms without definitions,

but one can hardly avoid the conclusion that the author himself had no very sharply cut ideas associated with the various terms. It is to be regretted that the table of "reduced luminous efficiencies" taken from Ives is not accompanied by a quotation to explain the significance of this important conception and its relation to the older ideas of luminous efficiency and the mechanical equivalent of light.

On page 64 the statement is made that Houstoun's and Strache's specifications of a standard of illumination in terms of radiation having a spectral distribution corresponding to the sensibility curve of the normal eye "consist in specifying the light standard by the least quantity of radiated energy which can produce the standard intensity." This is not true, and the error is especially striking because immediately preceding it is a whole page of discussion of "the most efficient possible radiation" as the basis of the Ives standard.

It should be noted that the luminosity curves given on pages 42 and 98 are not in the form at present accepted, since they were plotted from Koenig's data without correction for the dispersion of his prism. Incidentally the ingenious hypothesis of Dr. Bell that errors in heterochromatic photometry with the equality of brightness photometer are due to "the shifting of colors by contrast along the luminosity curve" can not be considered so well established as the author seems to think.

In view of the importance of the relation of the old English candle to the international candle now generally accepted as the unit of intensity in England and France as well as the United States, it is unfortunate that Professor Barrows has felt it necessary to give a new value for the old unit (p. 61) and has thus helped to perpetuate the mistaken impression that the value of the English candle has been intentionally changed. The fact is that the present unit is exactly the same as the old English candle to the degree of accuracy with which the British authorities could determine the proper average value of the old unit. Since there have been no British standard sperm candles made under authority of

law since 1898, and the German candle was superseded by the Hefner 25 years ago, it is to be hoped that makers of text-books will some time accept the simple ratios of units now in use and will cease to give confusing tables of uncertain historical ratios.

The middle portion of the book gives descriptions of a great variety of photometrical apparatus and a very complete exposition of various methods of calculating light flux and illumination. A number of tables summarize the published empirical data of the best-known illuminating engineers and are valuable as an approximate indication of the results to be expected from various types of illuminants and methods of installation. In an appendix are given several tables of constants which are useful in the calculation of illumination.

Two chapters devoted to principles of interior and of street illumination are largely quoted from papers of Mr. A. J. Sweet. Of 22 pages dealing with street lighting, 17 are copied verbatim. Since Mr. Sweet's papers were not intended to be text-books, it is no disparagement of his work to say that the chapter covers the subject very inadequately. That the opinions so fully quoted are not universally accepted is shown in a curious way. Mr. Sweet takes twelve pages to establish the conclusion that an angle of about  $65^\circ$  from the vertical "must be taken as a line of absolute prohibition" for high intensity in street lamps. "If it is to be exceeded at all, it may as well be entirely ignored," he says, and on the opposite page Professor Barrows gives a curve for a lamp which has 75 per cent. of its maximum candle-power as high as  $80^\circ$  from the vertical, with the statement that it "closely approximates the ideal conditions"!

The book as a whole would have been much improved by a thorough editing, for in many passages the language is crude, to say the least. It is marred also by an unusual number of typographical errors. Nevertheless, in spite of the many weak points, it must be granted that Professor Barrows has collected a large amount of valuable material, and it is to be hoped that future editions will enable

him to remedy defects both of form and of substance.

### SPECIAL ARTICLES

#### THE EFFECT OF ANESTHETICS UPON PERMEABILITY

THERE is much uncertainty as to the mode of action of anesthetics and particularly as to their effect upon permeability. While some writers hold that anesthetics increase permeability, others take the opposite view.<sup>1</sup> To clear up this confusion appears to be a necessary step toward a theory of anesthesia.

A definite solution of this problem seems to have been attained in the cases here described. This result is due to the employment of quantitative methods without which it would not have been possible.

The experiments were made by measuring the conductance of living tissues of a marine plant, *Laminaria*. Under the conditions of the experiment an increase or decrease of conductance signifies a corresponding increase or decrease of permeability.<sup>2</sup>

The anesthetics were mixed with sea water and sufficient concentrated sea water was then added to make the conductivity equal to that of sea water. The material was then placed in the mixture and its conductance was measured at frequent intervals.

Material having resistance of 1,000 ohms<sup>3</sup> was placed in a mixture of 990 c.c. sea water plus 10 c.c. ether, to which was added sufficient concentrated sea water to make its conductivity equal to that of ordinary sea water. In the course of 10 minutes the resistance rose to 1,100 ohms; in the next 10 minutes it fell to 1,070 ohms; in 20 minutes more to 1,020 ohms,

and in 20 minutes more to 1,000 ohms. In the next 20 minutes it dropped to 990 ohms, at which point it remained stationary for a long time. Subsequently it decreased very slowly, but at exactly the same rate as the control which remained in sea water during the experiment. After 24 hours it had the same resistance as the control.

In order to find out approximately what part of the resistance is due to the living protoplasm the tissue was killed at the end of the experiment by adding a little formalin: after rinsing well in sea water the resistance was 320 ohms. This represents the resistance of the apparatus and dead tissue; on subtracting it from the resistance previously given we obtain approximately the resistance due to the living protoplasm. This may be called the *net resistance* while the resistance before subtraction may be called the *gross resistance*. In this experiment, therefore, the net resistance before treatment with ether was 1,000—320=680 ohms and the net conductance  $1 \div 680 = .00147$  mho. The loss in net conductance due to ether is 13 per cent., which means a decrease of permeability amounting to 13 per cent.

It is evident that this decrease of permeability is completely reversible and involves no injury. The fact that after the resistance has fallen to a stationary point it is 10 ohms below the starting point does not indicate injury, but only an increase in the conductivity of the solution due to the evaporation of the ether.

In another series of experiments the effects of the evaporation of the anesthetic were avoided by constantly renewing the solution by means of a steady current. It was then found that the resistance, after rising rapidly to a maximum, remained stationary for a long time (often for two hours or more) at the maximum point, afterward falling slowly to the normal. This more prolonged exposure to the anesthetic seemed to produce no injurious effects.

In these experiments the amount of ether in the solution was 1 per cent. by volume. Smaller amounts of ether produced less effect:

<sup>1</sup> Cf. Höber, "Physikalische Chemie der Zelle und der Gewebe," Dritte Auflage, 1911, pp. 219, 223, 489; R. Lillie, *Am. Jour. Physiol.*, 29: 372, 1912; 30: 1, 1912; Lepeschkin, *Ber. d. bot. Ges.*, 29: 349, 1911.

<sup>2</sup> The method has been described in *SCIENCE*, N. S., 35: 112, 1912.

<sup>3</sup> All the figures in this paper refer to readings at 18° C.

below 0.2 per cent. little or no effect was observable.

Higher concentrations of ether give a very different result. With 3 per cent. by volume of ether the resistance rises very rapidly to a maximum (which is about the same as when 1 per cent. is used) and then falls very rapidly. But instead of stopping when the normal is reached the resistance continues to fall rapidly until death ensues. If the concentration of ether be increased the period during which the resistance remains above the normal becomes shorter until finally it becomes impossible to detect it even when readings begin 30 seconds after placing the tissue in the anesthetic. There is a corresponding increase in the rapidity of the fall of resistance and of the onset of death.

The decrease of permeability observed in these experiments may be easily and quickly reversed by placing the tissue in sea water. Is this also the case with the increase in permeability? This was tested in the following manner: The material was allowed to remain in the anesthetic until its resistance had fallen about 100 ohms below the normal (*i. e.*, below the resistance it had before being exposed to the anesthetic). It was then replaced in sea water and readings were taken at frequent intervals; recovery would be shown by a rise in resistance.

No such rise in resistance was observed. The experiment was varied by replacing the tissue in sea water after the resistance had fallen only 50 ohms below the normal and also by choosing a concentration of ether which caused the resistance to fall very gradually. Even then there was but rarely any sign of recovery and this was of short duration and small in amount.

Similar results were obtained with chloroform, chloral hydrate and alcohol, but not at the same concentrations: the concentrations which correspond to 1 per cent. ether are approximately as follows: chloroform 0.05 per cent., chloral hydrate 0.05 per cent., alcohol 3 per cent.

Two distinct effects are observable in these experiments. One is a toxic effect evidenced

by an increase in permeability, while the other involves a decrease of permeability. A very important question is, with which of these is the anesthetic action associated? Since the distinctive mark of an anesthetic is the reversibility of its action, it is not reasonable to suppose that this action is associated with an irreversible change in permeability. Such a change is in no way peculiar to anesthetics, but is common to all toxic substances. We are, therefore, forced to the conclusion that it is the reversible change, involving a decrease of permeability, which is associated with the anesthetic action.

The fact that typical anesthetics (ether, chloroform, chloral hydrate and alcohol) decrease the permeability of the tissue to ions is profoundly significant in view of the fact that the transmission of nervous and other stimuli is believed to depend on the movement of ions within the tissues. #### PARTIAL SEX-LINKAGE IN THE PIGEON

THAT certain characters in pigeons are sex-linked is shown by the work of Staples-Browne,<sup>1</sup> Cole<sup>2</sup> and Strong.<sup>3</sup> Both Staples-Browne and Strong, however, encountered certain exceptions which I shall try to show are explicable on the assumption that there is in the female pigeon a pair of sex-chromosomes, between which crossing-over of the factors may occur.

Staples-Browne found that a white female crossed to a dark male produced all dark offspring, showing that white is recessive to dark. The reciprocal cross, *viz.*, white male by dark female produced dark males and white females. So far, this last cross is a typical case of "criss-cross" inheritance, in which the recessive character entered the cross from the parent homozygous for the sex-differentiating factor, *viz.*, from the male in this case.

Staples-Browne found, however, in this *F*<sub>1</sub>, in addition to the white females, one dark fe-

<sup>1</sup> R. Staples-Browne, *Jour. Genetics*, June, 1912.

<sup>2</sup> L. J. Cole, *SCIENCE*, August 9, 1912.

<sup>3</sup> R. M. Strong, *Biol. Bull.*, October, 1912.

male, and Strong found three such dark females.

If in the female the sex-differentiating factor and the factor for plumage color are placed close enough together in the same chromosome to be linked, but not so close that the linkage is complete, "crossing-over" would cause the two factors which entered in the same member of the homologous pair of chromosomes to lie in different members and hence to segregate to different gametes.

If the sex-differentiating factor be  $M$ , then the formula for the male is  $MM$  and for the female  $Mm$ . Let the gene carried by the recessive white pigeon be  $w$  and the dominant form of that gene carried by the dark bird be  $W$ . The dark female would ordinarily form gametes of the types  $MW$  and  $mw$ , but would occasionally form gametes  $Mw$  and  $mW$  by crossing-over.

The gametes and their possible combinations would be as follows:

$P_1$	White ♂	$Mw—Mw$
	Dark ♀	$Mw—MW—mw—mW$
$F_2$	$Mw$	— white ♂ (exceptional)
	$Mw$	— dark ♂
	$MW$	— white ♀
	$mw$	— dark ♀ (exceptional)
	$Mw$	— white ♂
	$mW$	— dark ♀

A measure of the linkage between the sex-differentiating factor and the factor for plumage color would be the ratio of crossovers to the total number of individuals which might show crossing-over, viz., 4:59 or 7 per cent.

It should be pointed out that "partial-sex-linkage" signifies the linkage between the sex-differentiating factor and any other factor in the sex chromosome. In the case of *Drosophila* "sex-linked" means only that the factor is carried by the sex chromosome, and as yet no evidence has been obtained bearing on the degree of linkage of the sex-differentiating factor and any of the other factors thus far found in the same chromosome.

An explanation similar to the one here adopted for the pigeon may be given to Bateson and Punnett's<sup>4</sup> results with the silky fowl where partial-sex-linkage in the pigmentation is found. Three other cases of the same sort have been reviewed by Sturtevant,<sup>5</sup> viz., pink versus black eye in canaries, *Aglia tau* and its variety *lugens*, and *Pygæa anachoreta* and *P. curta*.

Two cases of partial-sex-linkage in which the male is heterozygous for sex are reported. At least Sturtevant<sup>6</sup> so interprets the case of the dwarf guinea-pigs of Miss Sollas, and quite recently Doncaster<sup>7</sup> finds in cats that certain exceptions in the inheritance of coat-color may be due to partial-sex-linkage.

COLUMBIA UNIVERSITY

#### EXPERIMENTS SHOWING THAT COMPLETE RELATIVITY DOES NOT EXIST IN ELECTROMAGNETIC INDUCTION

In the *Physical Review* for November, 1912, I described in detail some experiments which, taken together with earlier experiments by Faraday and others, establish the fact that complete relativity does not exist in electromagnetic induction. As a number of enquiries with reference to these experiments have been made, and as the subject of relativity is one in which great interest is taken by others as well as physicists, it seems desirable to give a brief account of the experiments in SCIENCE.

Two series of experiments were made, one without iron and the other with iron. In the first series a cylindrical condenser was mounted symmetrically in the approximately uniform magnetic field within a cylindrical electric coil coaxial with the condenser's armatures. The condenser, maintained at rest, was short-circuited, and the coil, tra-

<sup>4</sup> W. Bateson and R. C. Punnett, *Jour. Genetics*, August, 1912.

<sup>5</sup> A. H. Sturtevant, *Jour. of Exp. Zool.*, May, 1912.

<sup>6</sup> A. H. Sturtevant, *Am. Nat.*, September, 1912.

<sup>7</sup> L. Doncaster, *SCIENCE*, August 2, 1912.

versed by an electric current, was rotated about its axis at uniform speed. The inner armature of the condenser was then insulated from the outer, after which the magnetic field was annulled and the rotation stopped. The inner armature was then tested for electric charge.

The second series of experiments was similar to the first except that the magnetic field was produced by two symmetrical electromagnets mounted coaxially with the condenser and rotated together at the same speed.

In neither series of experiments was there detected upon the condenser any charge as great as the experimental error (see below).

Now it is an immediate consequence of the classical experiments of Faraday and others upon the electromotive force developed in a metal disc rotating in a magnetic field produced by a *fixed* electric coil or magnet, together with experiments of Blondlot,<sup>1</sup> H. A. Wilson,<sup>2</sup> and myself<sup>3</sup> upon the electric charges developed on adjacent conductors by the motion of insulators in magnetic fields produced by fixed coils or magnets, that, if the complete condenser and its short-circuiting wire had been rotated while the coil or magnets remained fixed, the armature tested would have received a charge equal to the continued product of the capacity of the condenser as it would be with air or free ether as dielectric, the magnetic flux through the space between the armatures, and the number of revolutions of the condenser per second. Moreover, it follows from the above mentioned experiments on insulators that if the condenser's dielectric is air, as in my own experiments, it is of no consequence whether the air rotates with the armatures or not.

It was thus easy to calculate the charge which would have been developed upon the condenser in each of my experiments for the same relative motion between it and the complete field-producing agent, but with this agent at rest and the condenser in motion.

The investigation proved conclusively that

<sup>1</sup> *Journal de Physique*, 1902.

<sup>2</sup> *Phil. Trans.*, 1904.

<sup>3</sup> *Physical Review*, 1908.

the condenser system, when it remained at rest and the agent producing the field rotated, received not more than a minute fraction of the charge it would have received for the same relative motion if the agent producing the field had been the part to remain at rest. Within the limits of error of the experiments—about 1.4 per cent. in the experiments with the electric coil, and about 1 per cent. in the experiments with the electromagnets—this fraction was zero.

The experiments appear to be *experimenta crucis*, in complete accord with the theory of Lorentz, but inconsistent with any theory based on complete relativity.

S. J. BARNETT

THE OHIO STATE UNIVERSITY

#### THE AMERICAN SOCIETY OF NATURALISTS

THE thirtieth annual meeting of the American Society of Naturalists was held at Case School of Applied Science, Cleveland, Ohio, on January 2, in connection with the meetings of the American Society of Zoologists, the American Association of Anatomists, the Botanical Society of America, the American Society of Physiologists, the American Society of Biological Chemists, the American Phycopathological Society, and the various sections of the American Association for the Advancement of Science.

The morning session was devoted to a symposium on Adaptation, with the following speakers:

M. M. Metcalf (Oberlin College): "The Origin of Adaptations through Selection and Orthogenesis."

Burton E. Livingston (Johns Hopkins University): "Adaptation in the Living and Non-living."

George H. Parker (Harvard University): "Adaptation in Animal Reactions."

Henry T. Cowles (University of Chicago): "The Adaptation Viewpoint in Ecology."

Alfred G. Mayer (Carnegie Institution of Washington): "Adaptation of Tropical Animals to Temperature."

Albert P. Mathews (University of Chicago): "Adaptation from the Standpoint of the Physiologist."

Lawrence J. Henderson (Harvard University): "The Fitness of the Environment; an Inquiry

into the Biological Importance of the Properties of Matter."

These papers will appear in the *American Naturalist*.

The afternoon session was for the reading of papers on Genetics, the program being as follows:

R. M. Strong (University of Chicago): "Sex-linked and Sex-limited Inheritance." Read by title.

L. J. Cole (University of Wisconsin): "The Reversionary Blue Pigeon."

B. M. Davis (University of Pennsylvania): "The Behavior of Hybrids of *Oenothera biennis* and of *O. grandiflora* in the Second and Third Generations."

George H. Shull (Carnegie Institution of Washington): (1) "Duplicate Genes for *Bursa pastoralis*." (2) "A Sex-limited Character in Plants."

R. A. Emerson (University of Nebraska): "The Inheritance of a Recurring Somatic Variation in Variegated Ears of Maize."

C. M. Child (University of Chicago): "The Fundamental Reaction System and its Significance in Inheritance." Read by title.

A. F. Shull (University of Michigan): "Inheritance of Egg Characters and the Sex-ratio in *Hydatina senta*."

J. A. Detlefsen (University of Illinois) (introduced by W. E. Castle): "Studies of a Cross between *Cavia rufescens* and the Guinea-pig."

K. Foot and E. C. Strobell (New York City): "Results of Crossing Two Hemipterous Species with Reference to the Inheritance of an Exclusively Male Character, and its Bearing on Modern Chromosome Theories."

H. K. Hayes (Connecticut Agricultural Experiment Station): "The Inheritance of Certain Quantitative Characters in Tobacco."

The annual dinner of the society was held on the evening of January 2, at the Colonial Hotel, one hundred and twenty-four being present. The president's address by Professor E. G. Conklin, on "Heredity and Responsibility," was published in *SCIENCE* for January 10.

The following new members were elected: Helen D. King, Wistar Institute; Lewis R. Cary, Princeton University; E. Newton Harvey, Princeton University; Ethel M. Browne, Princeton University; Aute Richards, University of Texas; Otto F. Kampmeier, University of Pittsburgh; C. G. Crampton, Massachusetts Agricultural College, Amherst, Mass.; H. F. Roberts, Manhattan, Kan-

sas; F. W. Bancroft, Rockefeller Institute; Caswell Grave, Johns Hopkins University, and H. L. Wieman, University of Cincinnati.

The following officers were elected for 1913:

*President*—Ross G. Harrison, Yale University.

*Vice-president*—E. M. East, Harvard University.

*Secretary*—B. M. Davis, University of Pennsylvania.

*Treasurer*—J. Arthur Harris, Station for Experimental Evolution, Cold Spring Harbor.

*Additional Members of the Executive Committee*—A. P. Mathews, University of Chicago, and A. L. Treadwell, Vassar College.

A. L. TREADWELL,  
Secretary for 1912

### THE AMERICAN MATHEMATICAL SOCIETY

THE nineteenth annual meeting of the American Mathematical Society was held at Cleveland, Ohio, in affiliation with the American Association for the Advancement of Science, on Tuesday-Thursday, December 31-January 2. The usual winter meeting of the Chicago Section was merged in this annual meeting. Separate sessions of the society were held on Tuesday morning, Wednesday morning and afternoon and Thursday morning. On Tuesday afternoon there was a joint meeting of the society with Sections A and B of the American Association, the Astronomical and Astrophysical Society of America and the American Physical Society. At this joint meeting the following papers were read:

E. B. Frost, vice-presidential address, Section A: "The spectroscopic determination of stellar velocities, considered practically."

R. A. Millikan, vice-presidential address, Section B: "Unitary theories in physics."

A. G. Webster: "Henri Poincaré as a mathematical physicist."

E. J. Wilczynski: "Some general aspects of modern geometry."

L. A. Bauer: "Cosmical magnetic fields."

G. E. Hale: "Preliminary note on an attempt to detect the general magnetic field of the sun."

The attendance at the several sessions of the society included sixty-two members. The chair was occupied in succession by Professors E. W. Davis, E. H. Moore, G. A. Bliss, and after the annual election by the president-elect, Professor E. B. Van Vleck. The following new members were elected: E. W. Chittenden, University of Illinois; C. S. Cox, Mulberry, Fla.; S. D. Killam, University of Rochester; J. T. Rorer, Philadelphia, Pa.; R. M.

Winger, University of Illinois. Sixteen applications for membership were received.

At the annual election, which closed on Thursday morning, the following officers and other members of the council were chosen:

*President*—E. B. Van Vleck.

*Vice-president*—M. W. Haskell, B. O. Peirce.

*Secretary*—F. N. Cole.

*Treasurer*—J. H. Tanner.

*Librarian*—D. E. Smith.

*Committee of Publication*—F. N. Cole, E. W. Brown, Virgil Snyder.

*Members of the Council*—F. C. Ferry, W. B. Ford, R. C. MacLaurin, Jacob Westlund.

The treasurer's report shows a balance of \$9,684.92, including the life membership fund of \$4,483.69. Sales of publications during the year amounted to \$1,730.94. The total membership of the society is now 680, including 64 life members. The total attendance of members at all meetings during the past year was 336, the number of papers presented 179. The library shows a marked growth, the number of catalogued volumes being now 4,560. Much of the increase is due to the generous gifts of several hundred volumes by Dr. Emory McClintock and Dr. G. W. Hill, ex-presidents of the society.

The following papers were read at this meeting:  
R. D. Carmichael: "On the numerical factors of the arithmetic forms  $a^n \pm b^n$ ."

R. D. Carmichael: "On non-homogeneous linear equations with an infinite number of variables."

R. D. Carmichael: "Note on Fermat's last theorem."

W. A. Hurwitz: "Mixed linear integral equations of the first order."

H. Galajikian: "On certain non-linear integral equations."

W. A. Hurwitz: "On Green's theorem for the plane."

Arnold Emch: "On some properties of closed continuous curves."

G. A. Miller: "The product of two or more groups."

J. E. Rowe: "Three or more rational curves in collinear relation."

F. R. Sharpe and F. M. Morgan: "Quartic surfaces invariant under periodic transformations."

H. M. Sheffer: "A set of postulates for the Boolean algebra."

J. R. Conner: "The rational sextic curve and the Cayley symmetroid."

J. R. Conner: "Multiple correspondences determined by the rational space septic."

L. E. Dickson: "Finiteness of the odd perfect and primitive abundant numbers with a given number of distinct prime factors."

L. E. Dickson: "Amicable number triples."

J. L. Coolidge: "A study of the circle-cross."

G. A. Bliss: "The relation satisfied by two dependent functions near a point at which both are singular."

J. A. Eiesland: "On the algebraic curves of a tetrahedral complex and the corresponding surfaces conjugate to it."

E. H. Moore: "On nowhere negative kernels."

Daniel Buchanan: "Oscillations near one of the isosceles triangular solutions of the three-body problem."

Peter Field: "On constrained motion."

G. C. Evans: "On the reduction of certain types of integro-differential equations."

J. A. Caparo: "Hyperspace and the non-euclidean geometry of four dimensions."

Jacob Westlund: "On the factorization of rational primes in cubic cyclotomic number fields."

E. L. Dodd: "An erroneous application of Bayes's theorem to the set of real numbers."

E. L. Dodd: "The validity of Bertrand's approximation leading to the probability integral."

Edward Kasner: "Equitangential trajectories in space."

C. J. Keyser: "Concerning multiple interpretations of postulate systems and the 'existence' of hyperspaces."

E. J. Wilczynski: "On a certain completely integrable system of linear partial differential equations."

L. C. Karpinski: "Algebra in the Quadripartitum numerorum of Johannes de Muris."

L. C. Karpinski: "Hindu numerals among the Arabs."

H. B. Phillips: "Directed integration."

Joseph Lipke: "Geometric characterization of isogonal trajectories on a surface."

J. B. Shaw: "Integral invariants of general vector analysis."

J. B. Shaw: "On non-linear algebras."

D. R. Curtiss: "Proofs of certain formulas suggested by Laguerre's work in the theory of equations."

Arthur Ranum: "On the projective differential classification of  $n$ -dimensional spreads generated by  $\infty^3$  flats."

I. M. Schottenfels: "Proof that there is but one simple group of order  $7! / 2$ ."

L. P. Eisenhart: "Certain continuous deformations of surfaces applicable to quadrics."

E. V. Huntington: "A set of independent postulates for 'betweenness.'"

A. B. Frizell: "Some terms in the expansion of the infinite determinant."

T. H. Gronwall: "On Weierstrass's preparation theorem."

T. H. Gronwall: "On series of spherical harmonics (second paper)."

Cora B. Hennen: "Transformations and invariants connected with linear homogeneous difference equations and other functional equations."

Harris Hancock: "Problems in arithmetical geometry."

Harris Hancock: "Generalization of a theorem due to Liouville or to Dedekind, with applications to the geometry of numbers."

W. D. MacMillan: "A proof of Wilczynski's theorem."

W. D. MacMillan: "On Poincaré's correction to Bruns's theorem."

W. B. Fite: "Some theorems concerning groups whose orders are powers of a prime."

L. L. Small: "Some generalizations in the theory of summable divergent series."

C. E. Love: "On the asymptotic solutions of linear differential equations."

Virgil Snyder: "Algebraic surfaces invariant under an infinite discontinuous group of birational transformations (second paper)."

L. L. Silverman: "On the equivalence of definitions of summability."

R. M. Winger: "Self-projective rational curves of the fourth and fifth order."

The next meeting of the society will be held at Columbia University on Saturday, February 22.

F. N. COLE,  
Secretary

### THE OHIO ACADEMY OF SCIENCE

THE twenty-second annual meeting of the Ohio Academy was held at Ohio State University, Columbus, O., on November 28, 29 and 30, the president of the society, Professor Bruce Fink, of Miami University, presiding. On Thursday evening an informal reception was given at the Ohio Union Club, where assignment of rooms were made to the visiting members, and a pleasant social period was thoroughly enjoyed by all. The sessions on Friday and Saturday were in the general lecture room of the Physics Building.

The address of President Fink on "Botanical Instruction in Colleges" occurred at 1:30 P.M., Friday, while the evening was given up to a dinner and smoker.

The complete program follows:

"New and Rare Plants added to the Ohio List in 1912," J. H. Schaffner.

"Some Applications of Biometry to Agricultural Problems," A. G. McCall.

"The Influence of Topography on Bird Migrations," Lynds Jones.

"Experiments in Fertilization," R. A. Buding-ton.

"Heredity (Eugenics)," W. F. Mercer.

"The Ohio Biological Survey," Herbert Osborn.

"Notes on some Rare Ohio Mosses," Clara G. Marks.

"Effect of Road Oil on Rubber Tires," Errol L. Fox and Chas. P. Fox.

"Notes on Ohio Oaks," W. R. Lazenby.

"The Mississippian-Pennsylvanian Unconformity and the Sharon Conglomerate," G. F. Lamb.

"The Primary Motor Column of the Central Nervous System of *Amblystoma* and its Relation to the Motor Nerves," C. E. Coghill.

"Note on the Tactile Reactions of some Orb-weaving Spiders in their Webs," W. M. Barrows.

"*Balanoglossus* and the Origin of the Central Nerve Tube in Vertebrates," M. M. Metcalf.

"Additions to the Cedar Point Flora," E. L. Fullmer.

"Seeds and Seedling of some Forest Trees," W. R. Lazenby.

"Lorain County Myxomycetes," F. O. Grover.

"The Cerebral Ganglia of the Frog Tadpole," F. L. Landacre and Marie F. McLellan.

"An Ancient Lake in Ohio with Uneven Shore-lines," Geo. D. Hubbard.

"Terraces associated with the Terminal Moraine near Delafield, Wisconsin," C. G. Shatzer.

"An Ecological Study of Forest Types near Columbus," F. B. H. Brown.

"Algae of Lorain County, Ohio, with Notes on their Distribution," Susan P. Nichols.

"Yerba Mate (Paraguay Tea)," Chas. P. Fox.

"Mississippian Conglomerates in Northern Ohio," G. F. Lamb.

"Charts illustrating Feeble-mindedness," W. F. Mercer.

"A Supernumerary Appendage in *Otocryptops sexspinosus*, and a Theory of Heterorhythmic Development," L. B. Walton.

"The Soaring Flight of Birds," Lynds Jones.

"The Aquarium at the Naples Station," Stephen R. Williams.

"Geography of the Balkan Peninsula" (lantern slides), N. M. Fenneman.

"A Botanical Survey of the Sugar Grove Region" (lantern slides), Robert Griggs.

"The Fauna of the Conemaugh Formation," Clara G. Marks.

"A Preliminary Report on the Crayfishes of Ohio," C. I. Turner.

"Induced Modifications in the Pigment Development of *Spelerpes* Larvæ," A. M. Banta.

"Review of the Genus *Dero* (Aquatic Oligochaetes) with a Description of Two New Species," L. B. Walton.

"The Composition of a Typical Prairie," J. H. Schaffner.

"A List of Plants Collected in Cuyahoga County and New to the County or to Ohio," Edo Claassen.

"The Effects of Changes in Sea Beds on the Fauna and Lithology of the Richmond Period," G. M. Austin.

"The Application of Physics to Agriculture," A. G. McCall.

"The Resistance of Aluminum Oxide Films,"  
H. E. Graber.

"The Differentiation of Diffraction Effects  
from the Extra Transmission of Electric Waves,"  
C. R. Weiland.

"The Spectrum of Cored Carbons," C. D. Coons.

"The Effect of a Constriction in a Discharge  
Tube," R. F. Earhart.

"The Production of Light by the Firefly," C.  
R. Fountain.

"The Hall Effect and Allied Phenomena in  
Magnetic Alloys," A. W. Smith.

"Twist in Nickel and Steel Rods due to a  
Longitudinal Magnetic Field," S. R. Williams.

"The Effects of Temperature and Potential on  
the Thermionic Emission Heated Wires," Charles  
Sheard.

"The Scattering of Gamma Rays by Matter,"  
S. J. Allen.

"Some Peculiarities of the High Frequency  
Graphite Arc," A. D. Cole.

#### DEMONSTRATIONS

Charts showing Distribution of Mitosis in the  
Central Nervous System of *Amblystoma* as Cor-  
related with Functional Development, G. E. Cog-  
hill and S. W. Camp.

A Supernumerary Appendage in *Otocryptops  
scaspius* (Chilopoda), L. B. Walton.

Fine Crystals of Hopeite and of Tarhuttite,  
Two Rare Hydrous Phosphates of Zinc from  
Africa, Geo. D. Hubbard.

Maps and Diagrams Illustrating an Ecological  
Study of Forest Types, F. B. H. Brown.

The committee on the State Biological Survey  
reported that a definite organization had finally  
been accomplished through the cooperation of  
twelve educational institutions of the state and  
that a limited fund would at once be available  
toward beginning the work. The survey will be  
in charge of the director, Professor Herbert Osborn,  
of Ohio State University, and an administrative  
board consisting of a representative from each  
cooperating institution. The report was accepted  
and the committee dismissed.

The society adopted resolutions expressing its  
sense of loss in the death of three members during  
the year, Dr. Joshua Lindahl, Dr. P. A. Hobbs  
and Dr. H. L. True. Dr. Lindahl served the  
society as its president in 1900, and during his  
residence in Ohio had always taken an active  
interest in the success of the academy.

A resolution requesting legislation along the  
following lines was also adopted:

*Resolved*, that it is the sense of this academy  
that the legislature of Ohio should pass a law  
designed to make it impossible for the insane, the  
feeble-minded and the confirmed criminals to  
propagate their kind. That to this end we com-  
mend to its attention and study the laws providing  
for sterilization already in force in six of the  
United States. That copies of this resolution be  
sent to the several county and city medical socie-  
ties of Ohio, asking their cooperation in the ac-  
complishment of this purpose.

After adopting additional resolutions expressing  
the appreciation of the society for the courtesies  
extended by the faculty and others connected with  
the university, and furthermore thanking Mr.  
Emerson McMillan, of New York, for his con-  
tinued donations to the research funds of the  
society, the academy adjourned to meet at Oberlin  
next November.

A department of physics was organized and  
21 new members added, making the total member-  
ship 214.

The following officers were elected for the  
coming year:

*President*—Professor L. B. Walton, Kenyon  
College, Gambier, Ohio.

*Vice-presidents*—(Zoology) Professor Charles  
Brookover, Buchtel College, Akron, Ohio; (Bot-  
any) Professor F. O. Grover, Oberlin College,  
Oberlin, Ohio; (Geology) Professor August  
Foerste, Dayton, Ohio; (Physics) Dr. T. C. Men-  
denhall, Ravenna, Ohio.

*Secretary*—Professor E. L. Rice, Ohio Wesleyan  
University, Delaware, Ohio.

*Treasurer*—Professor J. S. Hine, Ohio State  
University, Columbus, Ohio.

*Librarian*—Professor W. C. Mills, Ohio State  
University, Columbus, Ohio.

*Executive Committee*—(ex-officio) Professor L.  
B. Walton, Gambier, Ohio; Professor E. L. Rice,  
Delaware, Ohio; Professor J. S. Hine, Columbus,  
Ohio; (elective) Professor S. J. Allen, University  
of Cincinnati, Cincinnati, Ohio; Professor C. G.  
Shatzer, Wittenberg College, Springfield, Ohio.

*Board of Trustees*—Professor W. R. Lazenby,  
Ohio State University, Columbus, Ohio.

*Publication Committee*—Professor J. H. Schaff-  
ner, Ohio State University, Columbus, Ohio.

L. B. WALTON,  
*Secretary*

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

Several points of superiority render the

## Bausch<sup>and</sup> Lomb Convertible Balopticon

the best projection apparatus obtainable for work in the lecture room and laboratory. Here are some of these features:

1. It renders possible every known form of optical projection—lantern slide, opaque, microscopic, vertical, polariscopic and spectroscopic.
2. It provides a convenient and instantaneous interchange between all forms.
3. Its different parts are easily interchangeable, making it an easy matter to rearrange apparatus as desired.
4. It may be bought in simpler form and built up later.
5. Opaque objects and illustrations— $7\frac{1}{2}$  inch square, or smaller—can be projected in vertical or horizontal position—with the use of one or two mirrors, or with no mirror at all.
6. It is absolutely rigid and accurate in all adjustments—at the same time simple and easy of manipulation.

*The Superior Quality of Bausch & Lomb lenses, microscopes, field glasses, projection apparatus, engineering and other scientific instruments is the product of nearly Sixty Years' Experience.*

# File Your Data For Future Reference

Document  
Box

In the course of your work, or, even, in general reading, you find many articles and notes of interest which are valuable for reference. You want to keep these for future use but it is inconvenient to preserve entire magazines, probably, and, when you clip out the article you want, you often lay it aside and soon lose it.

In any event, an accumulation of clippings soon becomes a chaotic mass of papers among which it is difficult to find any particular one. Even if you keep the unclipped magazines, the situation is practically the same, for your article is buried among a great many others of no interest whatever, and, the greater your collection, the less chance you have of locating any article of value.

A filing box has been made to save the time and trouble of such a search. In this box, you can preserve pencil notes, photographs, pamphlets, blue prints, drawings, magazine clippings, or the entire magazine, for that matter, so that you can refer at once to any particular one you want.

You can classify the matter by species, States, years; you can index it alphabetically, in fact, you can arrange it in any form which suits you best and the articles will always be just where you can find them at any time.

This box is made by the JESSE JONES PAPER BOX CO., of Philadelphia, and it is made in several styles to meet the requirements of different classes of matter. One box will be found serviceable for a miscellaneous collection of records, another for papers of a uniform nature, and so on. Jones has an illustrated catalog which shows these boxes and it will be sent at your request. The coupon will bring it at once: mail it now.

## ATOMIC THEORIES OF RADIATION<sup>1</sup>

TWENTY years ago the system of theoretical physics seemed so complete as to justify the opinion, not infrequently expressed, that it was probable that the great discoveries in physics had all been made, and that future advances were to be looked for in the sixth place of decimals. And yet, in the very midst of these predictions, came the announcement, made just eighteen years ago this week, of Roentgen's discovery which showed that there were great mines of physical gold as yet unworked. Since that time discoveries of fundamental importance have followed one another with such amazing frequency that one who is at all familiar with the history of physics will scarcely challenge the statement that the past fifteen years is quite unparalleled in the number and the significance of its advances. At the present time, too, the air is full of suggestion of still more fundamental developments.

Most of these recent advances find a place under the general title, "The Triumphs of an Atomistic Physics." Within the past decade, the atomistic conception of matter has silenced the last of its enemies, and to-day we are counting the number of atoms and molecules in a given mass of matter with as much certainty and precision as we can attain in counting the inhabitants in a city. No census is correct to more than one or two parts in a thousand, and there

<sup>1</sup> Address of the vice-president and chairman of Section B—Physics—American Association for the Advancement of Science, Cleveland, December, 1912.

is little probability that the number of molecules in a cubic centimeter of a gas under standard conditions differs by more than that amount from 27.09 billion billion.

We have learned, too, a great deal about the insides of the atom. We have proved that it has electrical constituents, and that these also have an atomic structure. In other words, we have superposed upon an atomic theory of matter a much more fundamental and at the same time a much more simple theory of electricity. And we have found most convincing demonstrations of the correctness of the view that every electrical charge is built up out of an exact number of electrical atoms, and that every electrical current consists in some kind of a transport of these electrical atoms through the conducting body. In fact, we can now count the number of free electrons upon a small charged body as directly and as infallibly as we can count our fingers and toes.<sup>2</sup> We have measured, too, the exact value of this elementary electrical atom, and found it to be  $4.774 \times 10^{-10}$  absolute electrostatic units.<sup>3</sup>

Furthermore, we have added much to our knowledge about how atoms and molecules behave as aggregates. We have found the most convincing demonstrations, both quantitative and qualitative,<sup>4</sup> of the correctness of the fundamental assumptions of the kinetic hypothesis, and have proved experimentally that every molecule in a gas, whether of the size of the hydrogen unit or ten billion times as big, is endowed at a given temperature with exactly the same average kinetic energy of agitation. And we have measured with a fraction of a per cent. of accuracy the value of this universal constant.

Finally, we have tremendously extended

our kinetic conceptions of matter through the study of radioactive processes, and have recently actually seen on photographic plates<sup>5</sup> the tracks of alpha and beta corpuscles as they shoot out spontaneously from radioactive atoms with speeds undreamed of in connection with projectiles of any kind twenty years ago—speeds which are of the same order of magnitude as the velocity of light.

In a word the last fifteen years have shown the atomic and kinetic conceptions to be certainly the most fruitful, may we not also say the most fundamental conceptions, not excepting even the principle of the conservation of energy, which have ever been introduced into physical science. Only in one domain have atomistic points of view failed completely to possess the field, and that, oddly enough, the only domain in which they were securely entrenched two hundred years ago, but from which they were driven, apparently forever, at the beginning of the last century, by the epoch-making work of Fresnel and Young. Upon this lost domain of *radiant energy* they are now making renewed attack. It is my purpose to-day to survey this field of conflict and to endeavor to appraise the successes and failures of each of the opposing forces from the point of view of *experimental physics* alone.

My first observation is that in this attack upon the domain of radiant energy, atomistic conceptions do not at present show a united front. In other words, there is not one sharply defined atomistic theory, but there are five distinct brands of "quantum" theory of various degrees of concentration. These are alike in that they all have to do with certain assumptions as to the nature of radiant energy, or as to the conditions under which such energy is ab-

<sup>5</sup> C. T. R. Wilson, *Proc. Roy. Soc.*, Vol. 87, p. 277, 1912.

<sup>2</sup> *Physical Review*, XXXII., p. 349, 1911.

<sup>3</sup> *Physical Review*, 1913.

<sup>4</sup> *Popular Science Monthly*, LXXX., p. 417, 1912.

sorbed or emitted by atomic or sub-atomic oscillators. Let us glance in succession at these various atomistic theories and inquire, first, what are the experimental facts which have called these five different types of assumption into being.

1. The first and least concentrated form, namely, that of Planck,<sup>6</sup> grew out of the fact that we had two radiation formulas, (1) that of Rayleigh,<sup>7</sup> and (2) that of Wien,<sup>8</sup> the first of which fitted the experimental facts for long wave-lengths (for which, indeed, it was alone suggested), while the second fitted the experimental curve at the other end of the spectrum only, although it was originally hoped that it would give the correct distribution of energy throughout the spectrum. Wien's general formula had been deduced from his displacement equation—an equation which rests only on thermodynamic reasoning and the proved facts of radiation pressure—with the aid of two additional assumptions, namely, (1) that the velocities of gas molecules follow the Maxwell distribution law; and (2) that the frequency of the vibrations sent out from a given molecule depends only on the temperature. Since this equation failed at long wave-lengths, and yet contained no more *particular* assumptions than those just mentioned, and since the first of these assumptions is one which we have the best of grounds for making, there was nothing to do but to modify the last one. Planck modified it in such a way as to obtain an equation that would go over into Rayleigh's equation at long wave-lengths, and into Wien's at short wave-lengths. I do not mean to imply that this sort of crass empiricism is all that there is behind Planck's

<sup>6</sup> "Vorlesungen über die Theorie des Wärmestrahlung," 1906, and "Acht Vorlesungen," etc., 1910.

<sup>7</sup> Rayleigh, *Phil. Mag.*, 49, p. 539.

<sup>8</sup> Wien, *Wied. Ann.*, 58, p. 662, 1896.

equation. It is fair to point out, however, that this was the experimental situation which guided him in his search for a new radiation formula. His own argument is, in brief, somewhat as follows:

Boltzmann's identification of the concept of entropy in thermodynamics with the concept of probability in statistical mechanics, a step which Planck calls the "emancipation of the entropy concept from the limitations of man's experimental skill, and the elevation of the second law to a real principle," carries with it as a necessity not only the atomistic conception of matter, but also some sort of an atomistic conception of radiant energy. For the assigning of an exact numerical value to the probability of a given physical condition can be accomplished only by considering that condition as dependent on a finite member of equally likely possibilities or complexions. The greater the number of these complexions, the greater the value of the probability. For example, in the throwing of two dice, there are three equally likely complexions with which a throw of four dots can be realized, namely, a 3 with the first die and a 1 with the second, a 1 with the first and a 3 with the second, and a 2 with each. On the other hand, a throw of 2 dots can be realized through but one complexion, namely, a one with each. The probability, then, of a four-dot throw is just 3 times that of a two-dot throw. Now when the entropy of a physical condition is made to depend in this way on the probability of its occurrence, we see at once that entropy tends toward a maximum simply because a change to a new state will not take place unless that new state has a greater probability than the old one. But, says Planck, there is no way of making the appearance of a given physical condition in a system depend in this way upon a definite, countable number of

possibilities, except by conceiving the system to be made up of a definite number of concrete and definite elements—for a continuum can not have countable elements. Hence, an atomistic structure of the system is a fundamental condition for the representation of its entropy by a probability. All systems, then, which possess an entropy must possess an atomic structure. Now experiment justifies the carrying over of the entropy concept to an enclosure filled with radiant energy, for it is only in this way that the Stefan-Boltzmann law and the Wien displacement law, both of which are found experimentally to be correct, are deduced. Hence we are forced to conclude that an atomistic structure of some sort must be applied to radiant energy. Planck then proceeds to apply it as follows: He imagines an enclosure having perfectly reflecting walls to be filled with black-body radiation. In this enclosure, and in equilibrium with the black-body radiation, are linear electromagnetic oscillators of a given frequency  $\nu$ . The relation between the energy  $U_\nu$  in each oscillator of frequency  $\nu$ , and the energy per unit volume  $u_\nu$  of black-body radiation of frequency  $\nu$ , is given by the ordinary electrodynamic laws as,

$$U_\nu = \frac{c^3}{8\pi\nu^2} u_\nu.$$

in which  $c$  represents the velocity of light. Now let us call in the idea of *atoms of energy* and assume that each oscillator contains at each instant an exact multiple of an element of energy  $\epsilon$ . From a consideration then of the total number of oscillators, and the total number of energy elements in all the oscillators, we can obtain an expression, as in the case of the dice, for the total number of complexions of the system, that is, the total number of possible distributions of the energy elements among the oscillators. This leads to an expression

for the entropy of the system of the form

$$S = F\left(\frac{U}{\epsilon}\right).$$

But the second law of thermodynamics, as applied by Wien,<sup>9</sup> had shown that

$$S = F\left(\frac{U}{\nu}\right).$$

Hence we must place  $\epsilon = h\nu$ , that is, the energy element  $\epsilon$  is proportional to the natural frequency  $\nu$  of the oscillator, and the proportionality factor  $h$  is a universal constant, which Planck calls the *Wirkungs quantum*. He thus arrives at his celebrated formula for the relation between the density of black-body radiation and frequency, namely,

$$u_\nu = \frac{8\pi h\nu^3}{c^3} \cdot \frac{1}{e^{h\nu/ckT} - 1}$$

or the intensity  $E_\lambda$  of black-body radiation of wave-length  $\lambda$ , and temperature  $T$ , is

$$E_\lambda = \frac{2c^2h}{\lambda^5(e^{ch/\lambda kT} - 1)}.$$

This formula meets the requirements of passing over, at small values of  $\lambda T$ , into Wien's equation, namely,

$$E_\lambda = \frac{2c^2h}{\lambda^5} e^{-\frac{ch}{\lambda kT}},$$

and for large values of  $\lambda T$ , into Rayleigh's equation, namely,

$$E_\lambda = \frac{2ckT}{\lambda^4}.$$

To this brief sketch of the origin of Planck's equation should be added the statement that Planck<sup>10</sup> finds a further proof of the necessity of taking some such step as that which he has taken in the faultlessness of Jeans's logic<sup>11</sup> in showing that the Hamiltonian equations, combined with the theory of probability, lead inevitably to Rayleigh's radiation equation, which is contradicted by experiment. There is,

<sup>9</sup> Wien, *Wied. Ann.*, 52, p. 132, 1894.

<sup>10</sup> Planck, *Ann. der Phys.*, 31, p. 758, 1910.

<sup>11</sup> Jeans, *Phil. Mag.*, 18, p. 209, 1909.

then, nothing whatever to do, in his judgment, except to deny the general validity of the Hamiltonian differential equations, and this is precisely what he has done. Furthermore, the fact that his own equation goes over into Rayleigh's equation when  $h$  is made infinitely small, seems to him to show decisively that certain elementary radiation processes, which in Jeans's theory are assumed to be continuous, are in fact discontinuous.

Now it would be presumptuous in me to attempt to pass upon the cogency of these arguments, especially as they have been made the subject of review by the foremost of the world theorists, among them the late Poincaré.<sup>12</sup> Nevertheless I shall pause just long enough to express the inevitable point of view of every man who has worked long enough in a laboratory to know from painful experience how large is the entropy, *i. e.*, the probability of the event, that *experimental* results will come out differently from the way in which, according to the inevitable logic of things, they must come out, and that for the reason that in five cases out of ten, the inevitable logic of the experimentalist, at least, involves some undiscovered or unconsidered element. He is prone to wonder, therefore, whether even the theorist's inevitable logic is absolutely inevitable.

However, it should be said that Poincaré,<sup>12</sup> while stating that the assumption that physical phenomena do not obey laws expressible by differential equations would constitute the most profound revolution which physics has undergone since Newton's day, yet sees no way of escape from Planck's conclusion, unless it be found in the fact that to obtain the relation between his linear oscillator and the density of black-body radiation, Planck assumes the very electrodynamic laws the validity of

which he in the end denies. While this is indeed a weakness in his theory, it doesn't in any way affect his argument for the necessity of some such step as that which he has taken. To my own mind, the uncertainty in this last argument lies in the fact that the general validity of the law of equipartition of energy is assumed to be a necessary consequence of the Hamiltonian equations. If this be so, then the Hamiltonian equations certainly must go, for we have known for over thirty years that the law of equipartition can not have any general validity.

Planck has appreciated fully from the beginning the above-mentioned weakness in the method of development of his equation, and within a year<sup>13</sup> he has modified his statement of his theory in the endeavor to meet Poincaré's objection. The theory as outlined above implies that, since energy is always contained in the oscillator in exact multiples of an energy unit, both the absorption and emission of energy by the oscillator must take place in units—that is discontinuously. Planck now assumes that emission alone takes place discontinuously, while the absorption process is continuous. At the instant at which a quantity of energy  $h\nu$  has been absorbed, an oscillator has a chance of emitting the whole of its unit, a chance which, however, it does not necessarily take. If it in this way misses fire, it has no other chance until the absorbed energy has arisen to  $2h\nu$ , when it has again the chance of throwing out its 2 whole units, but nothing less. If again it misses fire, its energy rises to  $3h\nu$ ,  $4h\nu$ , etc. The ratio between the chance of not emitting when crossing a multiple of  $h\nu$ , and the chance of emitting, is assumed to be proportional to the intensity of the radiation which is falling upon the oscillator. This, then, is at present the most fundamental and the least revolutionary form of quan-

<sup>12</sup> *Journal de Physique*, Se. 5, Vol. 2, p. 5, 1912.

<sup>13</sup> Planck, *Ann. der Phys.*, 37, p. 642, 1912

tum theory, since it modifies classical theory only in the assumption of discontinuities in *time*, but not in *space*, in the emission (not in the absorption) of radiant energy.

When we lay aside all consideration of the origin of this theory, and ask for its experimental credentials, we find two great successes commonly attributed to it, (1) it gives a correct energy-distribution curve; (2) it enabled Planck to deduce from radiation constants a value of the elementary electrical charge which agrees within its own limits of uncertainty—about 4 per cent.—with the values obtained by other and more accurate methods. The first of these claims is apparently justified, though too much stress must not be laid upon it in view of, first, the origin of the equation, and, second, the fact that from the shortest observable wave-lengths, clear down to the longest visible red, Wien's equation also fits the facts perfectly for all temperatures up to those of the arc. In other words, from the experimentalist's standpoint Planck's equation may be considered as Wien's equation with but a small correction term applied to it at one end. Such correction terms can often be obtained from a great variety of assumptions.

The second claim can not be considered at all, since the deduction of the value of  $e$  from the radiation constants has nothing whatsoever to do with quantum theory. The result comes just as well from Rayleigh's equation<sup>14</sup> as from Planck's and the significance of the fact that the correct value of  $e$  is obtained is that for certain ranges of temperature the kinetic energy of an oscillator in equilibrium with a gas is indeed the same as the translational kinetic energy of a gas molecule. Further successes of Planck's theory will be con-

sidered after the discussion of the other atomistic theories of radiation.

2. The second of these theories is somewhat more radical than the first, and is, in fact, merely that originally proposed by Planck. It assumes that both emissions and absorption of energy are discontinuous in time. Despite the fact that Planck has renounced this point of view, the theory refuses to die. Nernst and most of the investigators who are working in specific heat relations still adhere to it. What is the experimental situation which seems to demand it? It is a situation brought about by the recent development of methods of studying specific heats at high and low temperatures. I refer especially to the liquefaction of hydrogen and helium. Let us consider first the simplest case, namely, that of the specific heats of gases.

One of the most brilliant triumphs of the kinetic theory was the prediction that the molecular heat of a monatomic gas should be 2.98 calories, or approximately 1 calorie per degree of freedom of the molecule, a prediction accurately verified by experiment. Next, the theory said that the molecular heat of a more complex gas should be as many calories as its molecule has degrees of freedom. If then the molecule of a diatomic gas acts like a rigid frictionless dumbbell, no energy whatever going into vibrations along the line of connection of its two atoms, or into rotations about this line as an axis, then its degrees of freedom should be three translational, and two rotational, and hence its molecular heat should be 5 calories, which is, as a matter of fact, the value found for all of the so-called permanent diatomic gases at ordinary temperatures.

Now, however, come the facts which call for some modification of the simple dynamical theory. We have long known that even at ordinary temperatures the molec-

<sup>14</sup> Einstein, *Ann. der Phys.*, 17, p. 132, 1905.

ular heats of gases like chlorine and bromine, which have more loosely connected atoms than have the so-called permanent gases, are nearly a calorie too high; that, further, they grow higher as the temperature rises. Recent work,<sup>15</sup> too, shows that as the temperature is slowly raised from 300° to 1,200° C. the molecular heats of all the permanent gases rise from 5 to 6 calories, while at the temperature of 2,000° C. they have gone up to nearly 7, just as though two new degrees of freedom had gradually been added. This we should expect if at high enough temperatures energy begins to go into vibrations of the atoms along their line of connection in the diatom. Very recent work,<sup>16</sup> too, which seems to be reliable, shows that when the temperature of the diatomic gas  $H_2$  falls from 200° absolute to 60° absolute, its molecular heat falls from 5 calories to 3 calories. In other words, at 60 degrees absolute, and presumably at lower temperatures,  $H_2$  acts like a monatomic gas.

Now, say the quantum theorists, all these facts are beautifully explained by our hypothesis. For, according to it, no atomic vibrator can absorb any energy at all except in whole units of size  $h\nu$ , or multiples of  $h\nu$ . The diatomic vibrator then, consisting of the 2 atoms of a diatomic gas, can absorb no energy at all from the molecular impacts experienced by the molecule as a whole, until the energy of these impacts exceeds  $h\nu$ . Then it begins to absorb, and as the temperature rises still farther the number of atomic vibrators which begin to take on an energy load increases as rapidly as it can in view of the limitations imposed by the law of distribution of energy among the molecules, and the necessity of absorbing only in whole

multiples of  $h\nu$ . In the end, as the temperature rises, each atomic vibrator takes on the share of the energy which properly belongs to it in accordance with the law of equi-partition. The atomic vibrators of the chlorine and bromine molecules begin to do this at lower temperatures than those of the other diatoms, because the bonds holding the chlorine and bromine atoms together are relatively weak, and consequently their *frequencies* are small. Hence the energy units  $h\nu$ , characteristic of these absorbers, are correspondingly small, and therefore the temperature at which the kinetic energy of the molecular impacts reaches this value is low.

The explanation of the fact that  $H_2$  acts like a monatomic gas at low temperatures is this. The two rotational degrees of freedom of the  $H_2$  molecule drop out at low enough temperatures, for the reason that these rotations correspond at a given temperature to a definite *mean* rotational frequency  $\nu$ , and when the energy of impact falls below this value of  $h\nu$  no energy can go into these rotations.

Coming now to the atomic heat relations of solid bodies, these have been much studied of late and are interpreted by Nernst and others in terms of this same form of quantum theory. Dulong and Petit's law of the equality of the atomic heats of the elements, and Kopp's law of the additive properties of atomic heats in compounds, were, until very recently, the most suggestive of the unexplained laws of experimental physics. Boltzmann<sup>17</sup> gave a fascinating interpretation of these relations by assuming that the atoms of solids have natural periods of vibration, and, if so, that they must be in thermal equilibrium with a gas when their mean vibratory kinetic energy is the same as the mean translational energy of the gas molecules. If this

<sup>15</sup> Nernst, *Zeit. f. Elek. Chem.*, 17, p. 272, 1911.

<sup>16</sup> Euken, *Ber. der Preuss. Akad.*, February, 1912, p. 141.

<sup>17</sup> Boltzmann, *Wien. Sitz. Ber.*, 63, 2 abt., p. 731.

be so the total energy content of an atom of a solid, in view of its three potential and three kinetic degrees of freedom, must be twice that of a molecule of a monatomic gas. In other words, the atomic heats of solids should be twice the molecular heats of monatomic gases, *i. e.*, they should be 6 calories, as in fact they are in most cases found to be. But brilliant and successful as was this stroke, it only made the abnormally small values of the atomic heats of the elements of low atomic weight (C, Bo, Si) the more inexplicable, especially after it was found that these substances all behave normally at high enough temperatures. Now the recent work of a number of experimenters, notably of Nernst<sup>18</sup> and his pupils, shows that at sufficiently low temperatures *all* substances show abnormally low atomic heats, and that, in general, the lower the atomic weight, the higher the temperature at which the abnormality begins to appear. This means that if a degree of rise in temperature means a given increase in the energy of vibration of the atoms of any substance, then at low enough temperatures only a fraction of the atoms take on their normal energy load. But this is precisely what the quantum theory demands. No atom can take on any energy at all until the impacts of the molecules of the surrounding gas possess an energy as high as  $h\nu$ , and hence the higher the  $\nu$  the higher the temperature at which energy can begin to be absorbed. Further, *ceteris paribus*, the smaller the atomic weight, the higher the  $\nu$  and hence the sooner, with decreasing temperature, should atomic heats lower than 6 calories begin to appear.

One can not withhold his admiration from the beauty of the qualitative agreement between this theory and experiment. But can the theory stand a quantitative

test? Such a test has been made as follows. Lindemann,<sup>19</sup> by assuming simply that a fixed relation holds at the melting point,  $T_s$ , of any substance between the amplitude of its atomic vibrations and the distance between its atoms, that is, its atomic volume,  $v$ , obtained without the aid of a quantum theory, a formula of the form

$$\nu \propto \sqrt{\frac{T_s}{mv^3}},$$

by which the frequency  $\nu$  in the solid state of an atomic vibrator of atomic weight  $m$  can be computed. This formula yields results which agree fairly well with direct measurements of  $\nu$  by means of "reststrahlen" wherever the latter have thus far been made. With the aid of this formula, then, we may first check our rough guess that the order of diminishing frequencies is the exact order in which atomic heats begin with decreasing temperature to fall below 6 calories, and, second, we may compare the frequencies computed by Lindemann's formula with those given by Planck's equation and the observed departure from Dulong and Petit's law at low temperatures. The method of doing this was pointed out by Einstein.<sup>20</sup> The agreement is sufficiently good to warrant the conclusion that the departures from Dulong and Petit's law are in fact fundamentally conditioned by atomic frequency. But it can not be said that Planck's equation, as applied by Einstein to the computation of the relation between atomic heats and temperatures, succeeds in predicting very accurately the observed curves.<sup>20</sup> Furthermore, the departures are in the same direction with all substances. They may be explained by introducing additional hypotheses into the quantum theory, as Nernst and Lindemann have

<sup>18</sup> Nernst and Lindemann, *Sitz. Ber. d. Preuss. Akad.*, XLII, p. 306, 1910.

<sup>19</sup> F. A. Lindemann, *Phys. Zeit.*, 11, p. 509, 1910.

<sup>20</sup> Einstein, *Ann. der Phys.*, 22, p. 180, 1907.

sought to do,<sup>21</sup> or by seeking for causes of these specific heat relations which have nothing to do with quantum theory. The one conclusion which this experimental work in atomic heats drives home is that the principle of equi-partition of energy, while valid when applied to atomic vibrators for certain ranges of temperature, has no general validity. This is, however, nothing new. If we can not get rid of it without a quantum theory, as Planck and Poincaré and Jeans all imply, then some form of quantum theory has been demonstrated to be a necessity. If these atomic heat experiments stood alone, however, I fancy that other and more easily visualizable explanations would be sought. For example, so far, they seem to be qualitatively consistent with an assumption like this, namely, that as the absolute zero is approached, the atoms begin to freeze together, and thus the number of effective carriers of energy is diminished. The higher the atomic frequency the higher the temperature at which this freezing-up process begins. The atoms of solids would then be imagined to freeze into rigid systems of continually increasing size, each system being endowed, however, with the kinetic energy of agitation appropriate to its temperature. It might then become possible, before absolute zero was reached, for the total kinetic energy content of the whole mass to become that of a single molecule of the surrounding gas. Such an hypothesis would seem to account well for the exceedingly high thermal conductivity of non-metals at low temperatures,<sup>22</sup> since the transfer of energy from point to point would be effected by a diminishing number of intermediaries as the temperature fell. If, however, a quantum theory must be

called in to account for phenomena in other fields, it is of course in the interest of simplicity to make it do service in the field of atomic heats as well. All that can now be said is that the attempts thus far made to apply it quantitatively in this field have not been particularly successful, though they have been sufficiently suggestive to stimulate to further experimenting. New data are sure to pour in rapidly in the near future.

3. We now come to the forms of atomistic theory which make radical assumptions regarding the distribution of radiant energy in *space*, rather than in *time*. The least radical of these, because the least general, is that of which Professor Bragg<sup>23</sup> is the most active exponent. It is frankly corpuscular. It was developed, however, with a view of explaining the properties of one type of radiation only, namely, X- and  $\gamma$ -rays, and at a time when there was some justification for regarding these as isolated phenomena. Recent developments have strongly emphasized the similarities, rather than the differences, between these and other types of so-called ethereal radiations. But this in no way weakens the positive arguments for a corpuscular form of X-ray. The most compelling of these arguments is as follows:

X-rays unquestionably pass over, or pass all but an exceedingly minute fraction of the atoms contained in the space traversed, without spending any energy upon them or influencing them in any observable way. But here and there they find an atom from which they hurl an electron with enormous speed. This is the most interesting and most significant characteristic of the X-ray, and one which distinguishes it from  $\alpha$ - and  $\beta$ -rays just as sharply as does the property

<sup>21</sup> Nernst and Lindemann, *Zeit. für Elektrochemie*, 17, p. 867, 1911.

<sup>22</sup> Eucken, *Ann. der Phys.*, 34, p. 185.

<sup>23</sup> Bragg, "Studies in Radioactivity," 1912.

of non-deviability in a magnetic field. For neither  $\alpha$ - nor  $\beta$ -rays ever eject electrons from the matter through which they pass with ionizing speeds. The energy which the X-ray or the  $\gamma$ -ray imparts to its chosen electron has been conclusively shown by many observers to be altogether independent of the intensity of the X-rays, and also independent of the nature of the atom from which the electron is hurled.<sup>24</sup> It depends solely upon the penetrating power, or hardness, of the X-ray. In fact, there is strong evidence now for the statement that although only a thousandth part of the energy of the cathode-ray beam in an X-ray tube is transformed into X-rays at the anticathode, yet when these same X-rays, weak in energy as a whole, fall upon matter outside the tube, they eject electrons from it with energies as great or nearly as great as those of the individual electrons of the original cathode rays.<sup>25</sup> It is as though the same energy were passed on in new form whenever an X-ray produces a  $\beta$ -ray, or a cathode-ray, an X-ray. These facts seem to be completely inexplicable on any sort of a spreading wave theory. The assumption of a continuous absorption by an atom of X-ray energy until the atom accumulates a sufficient store to eject an electron with the observed speed is completely untenable, for the time required for it to do this, according to the spreading pulse theory, would be longer than the life of any X-ray bulb, yet as a matter of fact this ejection begins the instant the X-ray bulb is started. Precisely the same argument holds for  $\gamma$ -rays. For these are found to eject electrons from matter through

which they pass with .9 the velocity of light. This corresponds to an energy of  $7 \times 10^{-7}$  ergs. According to Rutherford, the total energy of the  $\gamma$ -rays per gram of radium is  $4.7 \times 10^{-4}$  ergs, and if we assume that the number of  $\gamma$ -ray pulses is the same as the number of  $\beta$ -rays emitted, namely,  $7 \times 10^{10}$ , then the whole energy in a  $\gamma$ -ray is very nearly  $7 \times 10^{-10}$  ergs, i. e., it is precisely the same as the energy communicated by the  $\gamma$ -rays to the ejected electron even though this ejection may happen at a distance of 50 or 100 meters from the source. There is then no escape from the assumption in the case of X-rays, nor in the case of  $\gamma$ -rays, unless it be found in the uncertainty of the assumption of the identity of the number of  $\gamma$ -ray pulses and the number of  $\beta$ -rays, that the emitted energy keeps together as an entity, or quantum, which may be transformed back and forth between a  $\beta$ -ray and an X- or  $\gamma$ -ray. This energy is slowly dissipated into heat in its passage through matter while it is in the form of a  $\beta$ -ray, but apparently not at all while in the form of an X- or  $\gamma$ -ray. This argument is so close to the undeniable experimental facts, at least as they now stand, that if X- and  $\gamma$ -rays stood by themselves it is probable that there would be few opponents to Bragg's theory as to the corpuscular nature of these rays. His actual assumption is that X- and  $\gamma$ -rays consist of neutral doublets whose velocity determines the hardness of the ray. This is an assumption the truth or falsity of which could be tested if we could find the speed of X-rays. Opinion is still divided, however, as to the validity of conclusions drawn from the attempts that have been thus far made to identify the velocity of X-rays with the velocity of light.<sup>26</sup> Even

<sup>24</sup> Innes, *Proc. Roy. Soc.*, LXXIX., p. 442; Sadler, *Phil. Mag.*, March, 1910; Bestelmeyer, *Ann. d. Phys.*, 22, 429.

though these two velocities should be definitely proved to be the same, Bragg's argument for some sort of a corpuscular theory of X-rays would still stand.

But, aside from the minor difficulty of accounting for the so-called polarization of X-rays, that is, the dissymmetry of their emission about the point at which they originate, Bragg's theory encounters the supreme difficulty of accounting for the rapidly growing evidence of a complete parallelism between optical and X-ray effects. Thus:

(1) Ultra-violet light, like X-rays, ejects electrons with speeds which have been repeatedly shown to be completely independent of the intensity of the source. I have myself raised a doubt about this conclusion, but have recently shown that the doubt is unjustified,<sup>27</sup> and that the conclusion holds even when the intensity varies in the ratio 1,000 to 1.

(2) In the normal photo-electric effect, which has none of the earmarks of a resonance phenomenon, all observers now agree that the speeds of the ejected electrons increase regularly with the frequency of the light,<sup>28</sup> just as the speeds of electrons ejected by non-homogeneous X-rays increase with the hardness of the rays. Apparently, too, the law of increase is the same in each case.

(3) There is a selective photo-electric effect characterized by the emission at a particular frequency of the exciting rays of an abnormal number of electrons. This emission can not be excited until the frequency of the incident light reaches a definite value which is characteristic of the illuminated substance. This selective effect bears all the earmarks of an absorp-

tion band.<sup>29</sup> Precisely similarly there is a selective X-ray effect characterized by the emission at a given hardness of an abnormal number of electrons, and also by the excitation of a new type of X-ray radiation, which differs from the ordinary or scattered X-ray in being homogeneous, symmetrical about the origin, and having a penetrating power which is characteristic of the emitting substance instead of the quality of the exciting X-ray. This so-called homogeneous or characteristic X-radiation can not in general be excited until the hardness of the exciting ray exceeds a definite value. This critical value is nearly proportional to the atomic weight of the excited substance. The exciting rays experience absorption at the hardness at which the new increase in  $\beta$ -ray emission occurs. In other words, this selective X-ray effect, like the selective photo-electric effect, bears all the earmarks of an absorption band.<sup>30</sup>

(4) Light rays, X-rays and  $\gamma$ -rays all behave exactly alike in throwing more electrons forward in the direction in which the rays are moving than backward in the direction from which they came.<sup>31</sup>

(5) Finally, Laue, Friedrich and Knipping,<sup>32</sup> by using as a diffraction grating the regular arrangement of the molecules themselves in a crystalline substance, have recently obtained beautifully sharp photographic patterns which resemble very closely diffraction patterns in light. The wave-lengths of the X-rays computed from assumed intermolecular distances is about

10<sup>-9</sup> centimeters, or .0001 that of the shortest known ultra-violet waves. These experiments present strong evidence that some types of X-rays at least possess a periodic character. In a word, then, all these similarities suggest inevitably the hypothesis that ordinary scattered X-rays are white light, of short wave-length, and that characteristic X-rays are monochromatic light of short wave-length. If Bragg's neutral pair theory is to have any future, it must in all probability, then, be extended to all electro-magnetic radiations.

But how, when a charged pitch ball, for example, swings back and forth on its silk-thread suspension in our laboratories, are the periodic electromagnetic disturbances which it sets up in the neighborhood to be interpreted in terms of the emission of neutral pairs? No one is bold enough at present to attempt to thus resurrect a straight corpuscular theory of all ethereal radiation, with all that it implies regarding the dependence of the velocity of light, on the velocity of the source, the interpretation of interference phenomena in light and of Hertz's wave phenomena in the realm of wireless telegraphy. We need, then, a more general hypothesis than that of Bragg.

4. Such a general hypothesis was made by J. J. Thomson in his Silliman lectures in 1903.<sup>33</sup> It was, historically, the first form of the modern atomistic theories of radiation as regards space relations, although it is here treated in the fourth place, because it stands fourth in the violence of the assumptions involved. Like Bragg's theory, it postulates radiant energy which is emitted by the source in bundles or quanta, though no necessary multiple relationship was at first assumed between the different elements emitted by the same source. It goes farther than

Bragg's theory in endeavoring to reconcile this quantum notion with the wave theory by assuming a fibrous structure in the ether, and picturing all electromagnetic energy as traveling along Faraday lines of force conceived as actual strings extending through all space. This is nothing more than a new picture of the structure of the ether and one which is perhaps no more impossible than all its rivals. To the support of such a hypothesis are brought all the arguments urged for Bragg's theory, while the arguments which I have urged against Bragg's theory are removed. It may be difficult, not to say repugnant, to some of us to attempt to visualize the universe as an infinite cobweb spun by a spider-like creator out of threads that never become tangled or broken, however swiftly electrical charges may be flying about or however violently we enmeshed human flies may buzz, but such is the hypothesis, and the objections to it will be treated along with those of the next and most concentrated form of quantum hypothesis.

5. This was proposed by Einstein<sup>34</sup> in 1905, and is simply the J. J. Thomson theory of the discontinuous distribution of radiant energy in space, assumed still to be electromagnetic and hence to have a velocity independent of that of the source, with the addition of Planck's original assumption that a given source emits and absorbs energy in units which are multiples of  $h\nu$ . This amendment has apparently been accepted by Thomson and seconded by Larmor. For the energy units,  $h\nu$ , have had some experimental successes, the consideration of which it was thought best to defer to this point.

In the normal photo-electrical effect the kinetic energy of the escaping electron increases with the frequency of the incident

<sup>33</sup> "Electricity and Matter," pp. 63 et seq.

<sup>34</sup> *Ann. der Phys.*, 17, p. 132, 1905.

light, and the experimental evidence is now fairly strong, especially in view of the recent work of Hughes,<sup>35</sup> that it is directly proportional to  $\nu$ . This is what we should expect from the fact that the energy of an electron ejected by an X-ray is proportional to the energy of the cathode particle which produces the X-ray. For the ether disturbance set up by stopping a cathode particle corresponds exactly to the ether disturbance set up by a half swing of a vibrating electron. We may then compare roughly the wave-length of one of the prismatically resolved components of white light with the wave-length of a Röntgen ray impulse by comparing the half-period of the light with the time of stopping the electron. This time can be shown to be inversely proportional to the energy of the electron, *i. e.*, the frequency of the X-ray produced by stopping an electron may be taken as directly proportional to the energy of the cathode-ray particle producing it. If, then, an X-ray ejects an electron with an energy proportional to the energy of the original cathode ray, ultra-violet light should eject an electron with an energy proportional to its frequency. Notice that this result is obtained without the aid of Planck's equation, but rather immediately from the fairly well demonstrated inter-convertibility of X-rays and  $\beta$ -rays and the assumption that light rays are nothing but soft X-rays. But not only is the absorption of energy by an electron from a light wave proportional to  $\nu$ , its numerical magnitude is approximated at least by multiplying the frequency of the light by Planck's value of  $h$ . It is true there is here no accurate agreement as yet; for part of the energy absorbed by the electron is lost in getting out of the metal, and the exact amount of this loss has not been measured with as much accuracy as we hope

soon to be able to attain. Nevertheless the agreement is now sufficiently good (within some 70 per cent.)<sup>36</sup> to lend some support to the notion that the amount of energy actually absorbed from the light by the escaping electron is  $h\nu$ .

A still further test of the hypothesis can be made by computing the frequency of X-rays from the observed velocity of emission of corpuscles ejected by them; *i. e.*, from the potential difference between the terminals of the X-ray bulb which produces them. Thus we have

$$h\nu = \frac{hc}{\lambda} = eV,$$

or if  $V = 40,000$  volts (this would correspond to fairly hard X-rays such as Laue used),

$$\lambda = \frac{hc}{eV} = \frac{6.55 \times 10^{-27} \times 3 \times 10^{10}}{4.774 \times 10^{-10} \times \frac{40,000}{300}} = 3 \times 10^{-9}.$$

Laue<sup>37</sup> gets from his diffraction patterns wave-lengths ranging from 1.27 to 4.83  $\times 10^{-9}$ . Walter and Pohl's previous diffraction measurements<sup>38</sup> also gave a value of the order  $10^{-9}$ . This is certainly striking agreement, and lends some support at least to the attempts to extend Bragg's assumption of the inter-convertibility of X- and  $\beta$ -rays to the inter-convertibility of light rays and  $\beta$ -rays, or more generally, to the assumption that whenever an electron is emitted a quantity of radiant energy  $h\nu$  is absorbed.

Furthermore, according to the most recent experimental results it doesn't seem to make any difference in what form this energy approaches the atom which is to take it on and reemit it. Thus Whiddington<sup>39</sup> and Beatty<sup>40</sup> show that characteristic X-rays are excited either by other characteristic X-rays which are harder than

<sup>35</sup> Hughes, *l. c.*

<sup>35</sup> *L. c.*

those to be emitted, or by the direct impact of  $\beta$ -rays of a corresponding energy; and again, there is now good evidence to show that whenever an electron ionizes a gas its energy of impact must exceed  $h\nu$  where  $\nu$  is now the natural period of vibration of the resonator within the atom which is responsible for the selective photo-electric effect.<sup>41</sup> All of these results are certainly successes of Planck's "Wirkungs quantum"  $h$ , though in directions scarcely contemplated originally by the theory; for in Planck's theory it is the natural period of the oscillator which determines the emission of energy in units of size  $h\nu$ , but in the normal photo-electric effect the emitted electron has an energy which has nothing to do with its natural period, if it has one. It is rather the period of the incident waves which determine the energy with which the electron is ejected.

I think I have now stated most of the important experimental facts which we proposed at the outset to review in the light of atomistic theories of radiation. When we look back over these experimental data there are two main results which stand out conspicuously through it all. *The first is that neither atoms nor electrons appear to be able to absorb any energy until it comes to them in a certain degree of intensity, and this degree varies with different substances.* We see this in the realm of low intensity heat waves where, in the measurement of atomic heats, different kinds of atoms seem to take on their normal energy load at different stages, as temperature rises, the lighter atoms taking it on in this case last; we see it in the realm of high intensity heat waves, such as are dealt with in finding black-body radiation curves; we see it in the realm of photo-chemical or photo-electric radiations, where

different substances begin to emit electrons at different frequencies of the incident light; and finally we see it in the realm of X-rays, where different substances are excited to emit characteristic X-radiations at different hardnesses, the heavy atoms in this case responding last, instead of first. We see further that *one intensity factor  $h$  proves itself, to say the least, exceedingly useful in every one of these domains.*

The second important fact that stands out is this, that *in all types of experiments in which the absorption of energy results in the emission of electrons there is apparently a complete, or nearly complete, inter-convertibility of energy between an electron and a so-called ether ray, whether it be an X-ray or a light ray.* Now the first of these two facts is the one upon which one group of quantum theorists is focusing its attention and demanding a unitary theory which emphasizes primarily an emission of energy which is discontinuous in time. The second fact, and it is the one which is the more striking and the better established, is that upon which the other group of theorists is focusing its attention and demanding an atomistic theory of radiation as regards space relations. Now the fifth and last of the quantum theories which I have presented is that which, in view of both of these groups of facts, demands a quantum theory which combines both of these characteristics. *The facts which have been here presented are obviously most completely interpreted in terms of such a theory, however radical it may be. Why not adopt it? Simply because no one has thus far seen any way of reconciling such a theory with the facts of diffraction and interference so completely in harmony in every particular with the old theory of ether waves.* Lorenz will have nothing to do with any ether-string theory, or spotted wave-front theory, or electro-magnetic corpuscle theory.

<sup>41</sup> Franck u. Hertz, *Ber. d. D. Phys. Ges.*, 13, p. 967, 1911, and 14, p. 167, 1912.

Planck has unqualifiedly declared against it, and Einstein gave it up, I believe, some two years ago; and yet a quantum theory which fails completely to interpret or take any account of the most striking and the best established experimental fact which demands a modification of old theories, viz., the independence of the energy of emission of electron upon the intensity of the source, or, more generally, the inter-convertibility of  $\beta$ -rays and ether rays is, at best, a very impotent affair. If we are going to leave either of these two main groups of facts out of account I think almost any experimentalist would say that the first group (that having to do with the universal constant  $h$ ) can most easily be spared; for if we could have radiant energy localized in space we might possibly account for all the experimental facts without having it emitted by a given source in exact multiples of something, but spreading ether pulses which contain energy in multiples of something are certainly wholly inadequate. They go but a short way toward accounting for the present experimental situation. In conclusion then we have at present no quantum theory which has thus far been shown to be self-consistent or consistent with even the most important of the facts at hand, and yet it looks as though one had to come, and when it comes I can scarcely believe that it will be one of the milder forms. That we shall ever return to a corpuscular theory of radiation I hold to be quite unthinkable. The facts of the static field alone seem to preclude such a possibility. But I see no a priori reason for denying the possibility of assigning such a structure to the ether as will permit of a localization of radiant energy in space, or of its emission in exact multiples of something, if necessary, without violating the laws of interference. That no one has as yet been able to do this can

scarcely be taken as a demonstration that it can not be done. Fifty years ago we knew that such a thing as an atom existed, but we knew absolutely nothing about its structure, and it was customary to assume that it had none. To-day we know a great deal about the structure of the atom, but the position formerly occupied by it has been assumed by that thing which we call the ether. We know that there is a vehicle for the transmission of electromagnetic energy, but we know nothing whatever about its structure and it has been customary to assume that it has none. To deny the existence of this vehicle, which we have been in the habit of calling the ether, and to use the word "vacuum" to denote *all* the properties heretofore assigned to it by the experimentalist, viz., those of transmitting electromagnetic disturbances, is a bit of sophistry in which he is little interested. We seem to be on the eve of learning something more about the properties of this vehicle, call it by what name you will, than we have known heretofore. Certainly there has never been a time when physics offered such tasks to its followers as now, nor ever a time when it needed more and better brains applied to these tasks. It may be that "THOU art come to the Kingdom for such a time as this."

R. A. MILLIKAN

UNIVERSITY OF CHICAGO

#### EDUCATIONAL DIAGNOSIS<sup>1</sup>

UP till a score of years ago theories of intellectual and moral diagnosis suffered from two defects. They had not fully abandoned the notion that mysterious inner forces or agents existed—memory, attention, courage, imitativeness, constructive-

<sup>1</sup> Address of the vice-president and chairman of Section H—Education—American Association for the Advancement of Science, Cleveland, December, 1912.

ness, emulation, kindness, reasoning power and the like—each of which was a faculty or essence whose nature and degree of strength at any one time could be measured once for all. They had not even begun to abandon the notion that men were classifiable mentally into a rather small number of rather distinct types.

The early practise of diagnosis amongst psychologists, so far as there was any, consisted in inferring the condition of the individual's memory, imagination, power of attention, suggestibility and the like, from some facts in his behavior in which these magic powers "expressed" themselves, and in defining him as of this or that "type" on the basis of his divergence from the average in one or the other direction. Workers in schools who had progressed so far as to know of these practises either accepted their validity or distrusted them without knowing why they did so. The great majority of teachers continued to judge intellect, character and skill by the traditional means used and slowly improved by generation after generation since man could think and speak.

The active experimentation with objective "tests" of mental traits during the last score of years has shown that "goodness" of memory in the sense of a uniform power to hold all that is acquired, closeness of concentration in the sense of a uniform power to resist at will distractions of every variety and other similar general excellencies or defects, were myths. The measurements of correlations of the last decade have shown that "types" of attentiveness, of imagery and the like, and of intellect or character as a whole, either do not exist at all or are so complicated by intermediate conditions as to be of no service to thought or practise.

The experimentation with tests and the measurements of correlations began, how-

ever, with faith in the dogmas which they eventually disproved. The great majority of workers in the early days of tests assumed that certain formal general powers of mind existed, the strength of each being easily diagnosed by any one of its manifestations. Learning ten digits or nonsense-syllables was a test of "memory." He in whom the words violin, whistle, bell and brook aroused images of sound was thereby classified apart from him in whom they aroused images of sight. "Endurance" was measured by the ergograph, or by addition, or by the rate of tapping. Idiocy, imbecility and feeble-mindedness were three real entities, with symptoms awaiting our discovery. Even to-day much of this expectation that the intellectual and moral condition of an individual can be adequately described in adjectives, and manifests itself by the clear presence or absence of symptoms in the way that measles and smallpox do, remains.

Experimentation began to cure itself of these traditions as soon as it began to test the tests themselves. As fast as it abandoned the habits of assuming *a priori* what a certain fact in behavior signified concerning the individual's constitution, and sought instead to discover by exact—that is, quantitative—observation just what constitutional features it actually did go with, the older easy but false diagnosis was exposed and the basis for present and future achievement was laid.

Such studies of symptoms and tests are roughly of two sorts, those in which two distinct groups are compared in respect to the trait in question and in respect to the various possible symptoms of it, and those in which a long series of groups, each differing but little from the next in order, are so compared. In both cases certain principles of method are very desirable, almost necessary, because of the continuous grada-

tion of men in mental traits up and down from a common mediocre condition and the wide variability of the same person's performance in the same test.

In the case where two groups are compared in respect to some condition (call it  $T$ ) and in respect to some possible symptoms thereof (call them  $S_1, S_2, \dots, S_n$ ) it is almost imperative that the amounts of  $T, S_1, S_2$ , etc., possessed by *each individual* be at least roughly determined. Unless this is done we can not tell how symptomatic of  $T$  each  $S$  is, nor compare the significance of these  $S$ 's with others tested in some other investigations; we can only say of each of them that it is or is not, in some undefined degree, symptomatic of  $T$ ; and perhaps that it is more or less so than others of the  $S$ 's tested in the particular investigation. For example, in testing tests for general mental ability, Mr. Terman, who merely chose five very bright boys and five very dull boys without determining how bright or how dull they were, has left all his results undefined in quantity and incomparable with any one else's. An otherwise admirable study has thus had far less influence on educational diagnosis than it should have had. It is also desirable that the differences within either group in respect to  $T$  be small relatively to the difference between the central tendencies of the two groups, and that the extent to which each  $S$  separates the first from the second group be stated in an exact and commensurate quantity.

Unfortunately, the great majority of studies of sane *versus* insane, ordinary *versus* feeble-minded, bright *versus* dull, color-blind *versus* color-keen, musical *versus* non-musical, and the like, have left one or more of these three requirements unfulfilled.

I can not quote a study that is beyond reproach in all these respects, but the fol-

lowing facts from Dr. Simpson's test of tests of general intellectual ability will illustrate them roughly. Dr. Simpson defines the first of his two groups by the fact that they were all teachers or graduate students in a university. The group compared with them were all "men in New York City who had never held any position demanding a high grade of intelligence," who spoke "English as their mother tongue."

Two of them were persons earning comfortable livings for their families, but men recognized by their associates as being dull. Eleven others were staying at the Salvation Army Industrial Home at the nominal salary of \$1.00 per week in addition to board and room, until work could be secured. One of these held a somewhat responsible position at the time, acting as assistant superintendent of the home. He stood high in the most significant tests. The remaining seven were found in a mission on the Bowery where they were being helped somewhat until they could find employment.

As a measure of the extent to which each symptom or test separates the "Poor" from the "Good" groups, the degree of overlapping is taken. For example, the facts for four tests—giving the opposites of words, memorizing lists of words, marking the A's on a sheet of printed capitals, and discriminating lengths—were: The point reached by 50 per cent. of the "Good" group was reached by none of the "Poor" group in the opposite test or in memory of words; by 15 per cent. of them in the A test; and by 33 per cent. in the case of discrimination of length. The point reached by 76½ per cent. of the "Good" group was reached by none of the "Poor" group in the opposite test; by 5 per cent. in the case of memory of words; by 20 per cent. in the case of the A test, and by 62 per cent. in discrimination of length. The percentages of the "Poor" group reaching the points reached by 88 per cent. and by 94 per cent.

of the "Goods" are shown similarly in Table I.

TABLE I

*Percentages of the "Poor" Group Reaching Certain Points of the "Good" Group's Ability*

Percentages of the "Good" Group Reaching Certain Points on the Scales	Percentages of the "Poor" Group Reaching the Corresponding Points			
	Opposite Test	Memory of Words	A Test	Dis. of Length
50 per cent.	0	0	15	33 <sup>2</sup>
76½ per cent.	0	5	20	62 <sup>2</sup>
88 per cent.	0	10	25	73 <sup>2</sup>
94 per cent.	0	10	25	88 <sup>2</sup>

It is obvious that the opposite test is highly symptomatic of something which differentiates these two groups; that the tests in discrimination of length are not; and that the four tests are—in order of merit as symptoms—in the order named, giving opposites, memorizing words, marking A's and comparing lengths.

When a series of groups, each differing slightly from the next in order in the amount of the *T* or *S* taken as the basis of comparison, are used, the method of testing a symptom's significance is by its *correlations*—by the closeness of the correspondence of the rankings of the individuals in the *S*'s with their rankings in the *T*. Thus twelve of the "Good" group in the preceding illustration were ranked, each by all<sup>3</sup> the rest (they being somewhat acquainted with the others' abilities), for general intellectual ability. It is then possible, by means which I will not rehearse here, to measure the closeness of correlation or correspondence between the measure for each man that would have been so obtained had this "imputed intelligence" been determined from 12,000, instead of 12, judges of each man, on the one hand, and the measure obtained for him by repeated testing with any of the tests. These correspondences as calculated for the four tests

<sup>2</sup> Average of three series.

<sup>3</sup> Or nearly all.

mentioned were: 96 hundredths of perfect correspondence in the case of the opposites test, 93 hundredths in the case of the memory of words, 21 hundredths in the case of the A test, and apparently zero in the case of discrimination of length.

This method allows a very delicate choice amongst tests, provided adequate data are at hand.

Suppose, for example, that arithmetical ability is defined as the ability required by a given selected set of a hundred arithmetical tasks or problems. We can find which ten of these will serve best as a test of the ability measured by the entire hundred, by measuring a suitable group in respect to the entire hundred, and choosing that set of ten whose combined score correlates most closely with the combined score for the hundred (the pairing being by individual pupils). This method not only demands much time in experimentation and calculation, but also a thorough understanding of the general logic and technique of measuring relations, including the peculiar relation of resemblances or mutual implication. For example, suppose that twenty children, who had in a given year been absent, respectively, 100 days, 95 days, 90 days, etc., down to 5 days, attained, respectively, average academic grades of 74, 75, 77, 77½, 77½, 78, 78½, 78½, 79, 79½, 79½, 80, 80½, 80½, 81, 81½, 81½, 82, 83 and 85. The correlation by any of the stock methods comes out as 1.00, and the investigator might fancy that he had proved that for the school in question the mark to be received could be perfectly prophesied from, and was determined by the same causes as, the attendance record. Nothing of the sort, I assure you, is proved by this perfect correlation. It would perhaps puzzle some of us to tell just why.

The method of observing the correspondence of an individual's status in the trait

taken as a symptom with his status in other traits of whose condition it may be a symptom is of course of wider application than shown in the case supposed. An individual's status in anything may be thus compared with his status in anything else and the correspondence measured. Achievement in school studies may be compared with achievement in adult life; how far skill in motor control and craftsmanship is a symptom of ability in abstract intellectual operations may be determined; whether mental ability is or is not indicative of mental health may be decided; what an individual's interests mean for his capacities, or what his ability in any one test means concerning his ability in any other, may be found out.

One special application of the method of correlation is so important as to deserve separate mention. This is its use in testing a symptom by its correlation with some future condition. When a psychological or educational measurement of an individual enables us to make a successful prophecy concerning the individual's future and one that could not otherwise have been made, we have not only the most impressive but also the soundest proof of the significance of the symptom in question. Thus we rightly increase our faith in Mr. Courtis's analytic tests of arithmetical abilities, if we find that he is able to prophesy truly that a certain student's work in algebra will be greatly improved by certain specified drills in the fundamental operations in arithmetic, though the usual observations of her teachers gave no hint of this.

The most important accomplishment of the last decade's study of intellectual and moral diagnosis has been to establish principles of method for testing symptoms. But there has been also a substantial beginning

in accumulating facts of symptomatology which education and the other social arts can henceforth use. These I shall not try to summarize, but only to illustrate.

As our first illustration of the knowledge of intellectual diagnosis that has been attained and may be expected soon to be much increased, let us take the case of general intellect—the ability to manage ideas—the average station of a man in respect to that group of powers which we call intellectual.

In order to avoid technicalities and to gain clearness I shall go somewhat beyond the specific results obtained by Burt, Bonser, Norsworthy, Simpson, Spearman, Krueger, Peterson and myself in testing tests of general intellectual ability. I shall in fact be guilty of prophesying what would occur rather than measuring what has actually been found to occur. However, the prophecy follows by straightforward inferences from facts found by one or another of these workers. Moreover, since I shall be careful to underestimate rather than overestimate the closeness of the correlation between an individual's general intellectual ability and his ability in any of the tests, the prophecy will be safe as an argument that the results of the study of mental tests are beginning to be important for education and the other arts of social control of human nature.

Suppose the men and women of this audience were measured in respect to these eight tests, four trials of each being given:

1. Supplying words to make sense in mutilated passages, the four trials being of four grades of difficulty.
2. Giving the opposites of words, each trial comprising twenty words, the four trials being of four grades of difficulty.
3. Memorizing a given word in connection with a given form, as in Fig. 1, so as to give the former when the latter is presented (there being ten pairs in each "trial").

4. Selecting from 50 forms, as in Fig. 2, 25 forms previously shown and examined for a minute or two. The 25 forms are shown in Fig. 3.

FIG. 1

5. Marking the necessarily false statements in mixed series of false and true statements, the four trials being of four grades of difficulty.

FIG. 2

FIG. 3

6. Addition.

7. Doing what is directed in such instruction-sheets as:

Cross out the smallest dot . . .

How many ears has a cat

Make a line across this line |

etc., etc.

and

With your pencil make a dot over any one of these letters: F G H I J and a comma after the longest of these three words: boy mother girl. Then if Christmas comes in March, make a cross right here . . . . . but if not, pass along to the next question and tell where the sun rises . . . . . If you believe that Edison discovered America cross out what you just wrote, etc., etc.

8. Selecting valid from invalid reasons for a given fact, the four tests being of four grades of difficulty.

The time required would be approximately two hours, say thirty minutes a day on four days chosen at random.

From the combined score made by an individual in these eight tests, his general intellectual ability—his capacity, that is, for science, scholarship and the management of ideas of all sorts—could be prophesied with a surprisingly small error. Suppose that the general intellectual ability of the duller men who are able to look after and support themselves (men who though temperate and strong earn say \$400 a year in good times in New York City) be represented by  $a$  and that of Aristotle or Goethe by  $a + b$ , the difference,  $b$ , being 100. Then the amount of such ability assigned by the test alone would not, on the average, vary from the individual's true amount by more than 5; and would not vary therefrom by more than 14 in one case out of a hundred. The 5 and 14 are very cautious estimates, 4 and 11 being probably nearer what such an experiment would in fact reveal.

If each of us knew all in the company well and wrote down the names in an order of general intellectual ability, and if all of these orders were combined into an order representing the impartial judgment of the

total group about each of its members, this order would be hardly any truer than the order got by using the combined scores of the tests alone. The two orders would indeed be practically identical. There is excellent reason to believe that it is literally true that the result of two hours' tests properly chosen from those already tested gives a better diagnosis of an educated adult's general intellectual ability than the result of the judgments of two teachers or friends who have observed him in the ordinary course of life each for a thousand hours.

There might, of course, be amongst this group certain individuals of great but very highly specialized intellectual ability, as in music or military strategy or mathematics, who would be rated much lower by this team of tests than by the general test of life itself. There might also be certain individuals especially able in just the lines of intellect which these eight tests measure, but low in others, so that their rating by these tests would be much too high. However, such extremely specialized intellects seem to be rare, and this team of tests covers a wider range of the various factors to which men assign credit as intellectual ability than a superficial examination reveals. No student of the matter would pretend to diagnose a man's station amongst other men for total intellect perfectly in two hours, or in twenty! But we can by these tests measure approximately the general intellectual ability of educated men when personal knowledge of them and their achievements is lacking, and can enrich and improve on that knowledge, when it is present.

As a second illustration I choose the very practical case of prophesying how long a pupil will continue in high school.

Dr. Van Denburg secured certain information from each of a thousand pupils en-

tering the public high schools of New York City in February, 1906, and then kept track of the length that each continued in the high school. Consider first the significance of the pupils' answers to the following questions, obtainable in ten minutes or so on the very day that a pupil enters the high school: "What do you intend to do for a living?" "Do you intend to stay in high school four years?"

If we let a line two inches long represent eight terms or four years, and draw below it the lines representing the median length of stay<sup>4</sup> in high school of each of the groups of pupils defined by one sort of answer, we get the facts shown in Fig. 4.

FIG. 4

It is the case, of course, that the prophecy made for any individual is only one of probability. A pupil who reports herself as intending to complete the course may stay only a half year and a pupil who reports himself as intending not to complete the course may remain for four years. Only in the long run and on the average can we be certain that the latter will stay five times as long as the former. The expectation for the two groups is shown more

<sup>4</sup>That is, the length of stay that half of the pupils in the group in question stay longer and half not so long.

completely in Fig. 5, where the area over each successive fraction of the four years represents the percentage of pupils who drop out from high school during that frac-

FIG. 5a

FIG. 5b

tion of the four years. Thus the chance that the "no" pupil will drop out before the second half year is 58 out of 100, or almost five times the chance that a "yes" pupil will. The chance that a "no" pupil will stay four years is 7.3 out of 100 or less than one fifth the chance that a "yes" pupil will.

FIG. 6

An important negative fact in diagnosing the probable length of a pupil's stay in the New York City public high schools is shown in Fig. 6. Economic conditions, as measured by the family expense for rental, are seen to be insignificant.

In from one to three months after these pupils entered school they were rated by their teachers for ability, defined as follows: "Native ability apart from success or failure in any particular subject of

FIG. 7

study. Natural brightness." The median expectation of the top tenth and bottom tenth by the rating are as shown in Fig. 7, the detailed facts being given in Fig. 8.

For those of the pupils who stayed through the first term or nearly to its close so as to receive formal school marks in their studies, the relation of school achievement in the first term to length of stay was calculated. It is shown in part in Fig. 7 and Table II. Ten times as many of those marked below 50 leave in the first year as of those marked 90 or above. Of 115 pupils marked below 50 not one remained to graduate in four years. As the marks rise the percentage leaving in the early years steadily falls, and the percentage graduating, rises.

FIG. 8a

FIG. 8b

TABLE II

*The relation of First Term's Mark to Length of Stay in High School*

First Term's Average Mark	Percentages Leaving School Each Year After Entrance					Graduated
	Left During First Year	Left During Second Year	Left During Third Year	Left During Fourth Year	Remained Four Years Without Graduating	
Below 50	61	22	8	4	6	0
50 to 59	49					5
60 to 69	39					3
70 to 79	20					18
80 to 89	17					37
90 to 100	6	12	12	6	12	54

Such prophecies as these for New York City could easily be worked out for any community. They show that in the important matter of length of stay in school a pupil's career is far from being a matter of unpredictable fortuity. Useful diagnosis of him and prognosis concerning his high school career can begin before he sets foot in the school, and for that matter, as other facts could be adduced to show, before he is born.

These two specimens of recent work in educational diagnosis give a just notion of what may be expected from the scientific study of human capacities, interests and careers. The worker who will make repeated tests of the general intellectual development or the special school achievement of any hundred human beings for any five years of their lives, utilizing the logic and technique appropriate to mental and social measurements, may be sure of contributing to the advancement of educational science.

The work of observing and measuring the relations between traits of man's constitution, circumstances of his environment and events in his career, both as these happen in nature and as they are modified by ingenious experiment, is sure to increase our knowledge of his nature and our power over his fate. It will not be long before the members of this section will remember with amusement the time when education waited for the expensive test of actual trial to tell how well a boy or girl would succeed with a given trade, with the work of college and professional school, or with the general task of leading a decent, law-abiding, humane life.

This work of testing tests—of measuring the relations of this and that feature of a man's educational life-history—has been neglected by many of the ablest students of human nature and education, partly, I think, because it seems to lack the inspiration of sweeping theories and the drama of immediate consequences. From the ordinary point of view it is a little trivial and tedious. But in the sense that the law of gravitation has a grandeur far beyond that of the heavens—in the sense that a change in the death-rate is the most truly dramatic event in nature—in this sense the task of testing tests gives way to no scientific work in dignity and humaneness. Tables of cor-

relations seem dull, dry, unimpressive things beside the insights of poets and proverb-makers—but only to those who miss their meaning. In the end they will contribute tenfold more to man's mastery of himself. History records no career, war or revolution that can compare in significance with the fact that the correlation between intellect and morality is approximately .3, a fact to which perhaps a fourth of the world's progress is due. Experiments measuring the effects of school subjects and methods seem pedantic and inhuman beside the spontaneous tact and insight of the gifted teacher. But his personal work is confined by time and space to reach only a few; their results join the free common fund of science which increases the more, the more it is used, and lives forever.

E. L. THORNDIKE

#### W. G. WRIGHT

WILLIAM GREENWOOD WRIGHT died on Sunday afternoon, December 1, 1912, in the eighty-third year of his age. He had been in apparently good health and spirits for some time past. He was found dead sitting in his chair, a newspaper fallen from his relaxed grasp. The cause was heart failure.

He was born near Newark, New Jersey; his early education was limited. He was a soldier in the Union army during the civil war, and soon after the close of that conflict he must have come to California, where he resided a few years in Los Angeles, where his only child was born and died in infancy. He went to San Bernardino about 1873, where he resided until his death and where he conducted a planing mill. About fifteen years ago he retired from active business, and spent his time in collecting and gathering material for his work on butterflies. His wife died a number of years ago, and he leaves no near relatives.

His collection of butterflies and library he has left to the California Academy of Sci-

ences, San Francisco. Some other collections are to be sold. Mr. S. B. Parish, the noted botanist, and the executor of Wright's estate, has given me the few data now obtainable.

W. G. Wright traveled all over the west coast from Alaska to Mazatlan, Mexico, collecting specimens in various departments of natural history, but especially the Lepidoptera. He published an interesting account of his travels in Mexico in *Zoe*. An article in the *Overland Monthly* for 1884 is entitled "A Naturalist in the Desert," and an article on "Collecting in Alaska," which can not now be located. Other papers are found in *Entomologica Americana*, *Canadian Entomologist*, *Papilio*, *Entomological News* and Edwards's "Butterflies of North America." Perhaps the most important service he rendered to science was the help he gave to W. H. Edwards in the great work just mentioned. In the *Ornithologist and Oologist*, for February, 1885, we find an article on "An Experiment in Bird Taming," with *Phainopepla nitens*; his name is frequent in the two large volumes, "Botany of California," as he was an enthusiastic collector of plants. His most important book, "The Butterflies of the West Coast," was published in San Francisco in October, 1905, and was really an epoch-making publication, notwithstanding the numerous inevitable mistakes. This work was illustrated entirely by color-photography.

Among the insects which have been named in his honor by different men, are: *Melitaea wrightii*, *Copæodes wrightii*, *Gluphisia wrightii*, *Leptarctia wrightii* and *Selidosema wrightiarum*. He named a number of new species, but a good many of these, especially those in his 1905 book, are synonyms.

Mr. Wright was a close friend of the two noted pioneer botanists and collectors, Edward Palmer and C. C. Parry, and made many excursions, of varying lengths, with them. He knew many other botanists and entomologists also.

W. G. Wright will always be remembered by those who were so fortunate as to have known him personally. He was a *naturalist*

in the true sense; such naturalists becoming fewer as the years pass.

The captains and the kings depart.

FORDYCE GRINNELL, JR.

PASADENA, CALIFORNIA

#### SCIENTIFIC NOTES AND NEWS

SIR HENRY ROSCOE celebrated his eightieth birthday on January 7 at Woodcote Lodge, West Horsley. His former pupils and friends have resolved to commemorate the occasion by presenting his bust to the Chemical Society of London. A deputation headed by Sir Edward Thorpe went to Woodcote and presented an address of congratulation.

THE twenty-fifth anniversary of Professor Charles Richet's appointment to the chair of physiology at the Faculté de médecine de Paris was celebrated on December 22. He was presented with a *Festschrift* containing some eighty contributions from distinguished physiologists, and addresses of congratulation were made.

CAPTAIN ROALD AMUNDSEN received the gold medal of the American Geographical Society on January 14, when he addressed in Carnegie Hall an audience of 3,000 persons. He will receive the gold medal of the Geographical Society of Chicago on February 3. He will be the first to receive this medal, as he was the first to receive the Culver Gold medal in 1907.

PROFESSOR GEORGE C. COMSTOCK, director of Washburn Observatory, University of Wisconsin, has been elected a fellow of the American Academy of Arts and Sciences.

DR. GEORG CANTOR, professor of mathematics at Halle, has been made an honorary doctor of the University of St. Andrews.

MAJOR SIR RONALD ROSS, F.R.S., has been appointed physician for tropical diseases to King's College Hospital, and will take up his duties in the autumn, after the removal of the hospital to Denmark Hill. Sir Ronald Ross is now professor of tropical sanitation in the University of Liverpool.

PROFESSOR FRANZ BOAS, of Columbia University, has been appointed lecturer in anthro-

pology at Harvard University for the second half year.

At the recent meeting of the American Phytopathological Society at Cleveland the following officers were elected for 1913:

*President*—F. C. Stewart, New York Agricultural Experiment Station, Geneva, N. Y.

*Vice-president*—Haven Metcalf, U. S. Department of Agriculture, Washington, D. C.

*Secretary-treasurer*—C. L. Shear, U. S. Department of Agriculture, Washington, D. C.

*Councillor*—W. J. Morse, Agricultural Experiment Station, Orono, Me.

The society decided to hold its next annual meeting at Atlanta, Georgia, in conjunction with the American Association for the Advancement of Science.

PROFESSOR A. S. HITCHCOCK, systematic agrostologist, U. S. Department of Agriculture, has returned from the West Indies. He visited Jamaica, Trinidad, Tobago and, incidentally, Cartigena and Puerto de Colombia. In Jamaica 643 numbers of grasses were obtained, representing about 168 species, and including all except four of the species known from this island, and many species not hitherto recorded. From Trinidad 337 numbers were collected, representing 140 species, and from Tobago 90 numbers representing 65 species. Mr. Hitchcock was successful in recollecting nearly all the species whose type localities are in these islands.

PROFESSOR WILLIAM J. G. LAND, of the department of botany of the University of Chicago, has returned with a large collection of botanical specimens from Australia and the islands of the Pacific.

MR. A. C. VEATCH, formerly chairman of the Land Classification Board of the United States Geological Survey, has arrived at the Cosmos Club, Washington, D. C., from London. He expects to spend a short time in the United States looking for men to assist him in his geological investigations, which have extended to many parts of the world.

PROFESSOR J. E. DUERDEN, Rhodes University College, Grahamstown, South Africa, has been invited by the government of British

East Africa to visit the protectorate to lecture and advise upon ostrich farming.

THE president of the British Board of Education has appointed an advisory council for the Science Museum, London. The council will be asked to advise the board on questions of principle and policy arising from time to time and to make an annual report on their proceedings to the board, together with any observations on the condition and needs of the museum which they may think fit to make. The following will be the first members of the council: Sir Hugh Bell, Bt., chairman; Mr. R. Elliott Cooper; Dr. J. J. Dobbie, F.R.S.; Mr. W. Duddell, F.R.S.; Mr. E. B. Ellington; Sir Maurice FitzMaurice; Sir Archibald Geikie, F.R.S.; Dr. R. T. Glazebrook, F.R.S.; Sir Alfred Keogh; Sir William Mather; Sir John Murray, F.R.S.; Sir William Ramsay, F.R.S.; Sir Henry E. Roscoe, F.R.S.; and Sir William H. White, F.R.S. The secretary will be Captain H. G. Lyons, F.R.S., of the Science Museum.

PROFESSOR CHARLES S. MINOT, who is now serving as the Harvard Austausch-Professor at Berlin, delivered from December 16 to 21 six lectures on "*Moderne Probleme der Biologie*" before the University of Jena. The subjects were:

1. The new cell doctrine.
2. Cytomorphosis.
3. The doctrine of immortality.
4. The development of death.
5. The determination of sex.
6. The conception of life.

The lectures were delivered before the university in the Aula and were attended by both students and professors. At the third lecture the Grand-duke of Saxe-Weimar was present in his official capacity as rector of the university. It was at his suggestion that the arrangement was made with the Prussian ministry of education by which the Harvard professor was to visit Jena, as an acknowledgment of the visit to America of Professor Eucken, who is a member of the philosophical faculty of Jena. It is the first time that an American exchange professor has served offi-

cially at any German university besides that at Berlin. Professor Minot's lectures were delivered in German and will be published shortly by the firm of Gustav Fischer.

UNDER the auspices of the department of geology of Columbia University, Professor William Morris Davis delivered a series of three lectures from January 14 to 16 on "Dana's contribution to Darwin's theory of coral islands," "The Valley of the Armançon: a study in physiographic analysis," and "The principles of geographical exposition." On January 17 Mr. Donald F. MacDonald, geologist of the Panama Canal, addressed the students of the department on "The general geology of the Panama Canal Zone."

DURING the week of December second, Dr. S. W. Williston, professor of vertebrate paleontology in the University of Chicago, gave the annual Sigma Xi lectures in a circuit composed of Washington University, University of Missouri and the University of Kansas. His subjects were "The Earliest Land Animals" and "The Evolution and Distribution of the Earliest Land Animals."

DR. GEORGE C. COMSTOCK, of the University of Wisconsin, gave the Sigma Xi address at Purdue University on January 17, his subject being "The Study of the Stars."

DR. J. A. DETLFSEN, of the Agricultural College of the University of Illinois, has delivered a series of lectures before the Kansas Agricultural Board and University on "Genetics in the Agricultural College."

PROFESSOR H. J. WHEELER, manager of the agricultural service bureau of the American Agricultural Chemical Company, Boston, Mass., lectured on the eighth inst. before the New Jersey State Board of Agriculture on "Some Interrelations of Plants, Soils and Fertilizers."

MR. S. A. COURTIS, head of the department of science and mathematics in the Home and Day School of Detroit, and supervisor of testing work in the Boston public schools, spoke on January 17, under the auspices of the Harvard chapter of Phi Delta Kappa, an honor society in the division of education. Mr.

Courtis has tested the mathematical ability of several thousand school children in New York and Boston, and described the results of his tests.

DR. R. RUGGLES GATES, lecturer in biology, St. Thomas Hospital, London, is giving a course of lectures on heredity and mutations at the Imperial College of Science and Technology.

THE fourth centenary of the birth of Andreas Vesalius, the pioneer of modern anatomy, will be celebrated this year with appropriate ceremonies at Brussels.

THADDEUS S. C. LOWE, of Los Angeles, chief of the aeronautic corps of the U. S. Army during the civil war, died on January 16, in his eighty-first year. Mr. Lowe made inventions in various fields, including balloons and instruments for atmospheric investigation, and artificial ice, metallurgical and water-gas apparatus. He built the Mount Lowe railway and established the Mt. Lowe Observatory in the Sierra Madre Mountains.

PROFESSOR GEORGE AUGUSTUS KOENIG, professor of chemistry at the Michigan College of Mines since 1892, and previously professor of mineralogy and metallurgy in the University of Pennsylvania, died on January 14, aged sixty-eight years.

M. LOUIS PAUL CAILLETET, the distinguished French chemist, known especially for his work on iron and acetylene and on liquefaction of gases, has died in his eighty-first year.

THE death is also announced of M. Léon Teisserenc de Bort, the French meteorologist, known especially for his work with captive balloons.

DR. OTTO SCHOETENSACK, professor of anthropology at the University of Heidelberg, died on December 23 in his sixty-third year.

DR. YUJIRO MOTORA, professor of psychology in the University of Tokyo, died on December 12. Dr. Motora took the doctor's degree in psychology about twenty-five years ago at Johns Hopkins University.

FREDERIK HJALMAR JOHANSEN, who accompanied Dr. Johansen in sledge journey across the North Polar ice, and Captain Amundsen

on his recent Antarctic expedition, has died at the age of forty-six years.

WE regret also to announce the death of Dr. E. Tavel, professor of surgery at Bern, and Dr. G. Tilling, professor of surgery at St. Petersburg.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE Rev. John Henry Ellis, of Collingham-gardens, South Kensington, has left, subject to his wife's life interest, the residue of his property, which will amount to not less than £90,000, to Cambridge University, "to be enjoyed and applied both as to capital and income by them for the general purposes of the university, in such manner as they may think fit."

AN anonymous graduate has given Harvard University \$50,000 for a building for the department of music, and other graduates and friends have subscribed as an endowment fund for its maintenance more than \$50,000. It will be used for the courses in the theory and history of music, the only branches of that subject which are taught at Harvard. It will have a hall of suitable size for chamber concerts, in which will probably be installed a pipe organ. The building will also be the headquarters for the musical organizations of the university.

YANKTON COLLEGE has received from Mr. James J. Hill an offer of \$50,000 for increasing the endowment, conditioned on the raising of \$200,000 in addition, within two years.

BATES COLLEGE dedicated on January 14 its new science building, Carnegie Hall. President George C. Chase gave a brief historical address, outlining the growth of the scientific departments at Bates in recent years, and telling of the efforts necessary to raise the \$100,000 in order to claim Mr. Carnegie's gift of \$50,000. Professor William T. Sedgwick, of the Massachusetts Institute of Technology, gave the formal address, taking as his theme, "The Interpretation of Nature."

At the winter meeting of the board of trustees, Cornell University, held in New York on January 18, the election of a dean of the faculty of arts and sciences was referred to

the faculty with power. This is in accordance with the recommendation made by President Schurman in his last annual report. Hitherto the deans have been nominated by the president and appointed by the trustees.

At Harvard University Dr. L. J. Rhea has been appointed assistant professor of pathology, and Dr. Dunham Jackson instructor in mathematics.

DR. ALEXIS HARDING, of Geneva, N. Y., has been appointed to the department of dairy husbandry in the Agricultural College of the University of Illinois with the title of professor of dairy bacteriology in the college and chief in dairy bacteriology in the station.

DR. KARL M. WIEGAND has been appointed professor of botany in the State College of Agriculture of Cornell University.

#### DISCUSSION AND CORRESPONDENCE

##### UNDERGRADUATE RESEARCH WORK IN MEDICAL SCHOOLS

TO THE EDITOR OF SCIENCE: A recent article in SCIENCE (November 29, 1912) by Mr. Drinker comments upon "Undergraduate Research Work in Medical Schools." In this article I find certain points that deserve comment. One of these points is this:

If we classify all these schools upon the basis selected by Mr. Flexner in the first report of the Carnegie Foundation in Medical Education, namely, upon the possession or lack of a two years' college entrance requirement, we find that of the schools permitting undergraduate research five fail the test.

The University of Cincinnati is one of the five. Another point is contained in the clause, "Schools permitting research and giving no visible time for it," etc.

I desire to point out that unless qualifications are added to such statements they are very misleading; and also I desire to point out that making the point of a one-year or a two-year requirement means absolutely nothing unless the facts concerning the enforcement of such a requirement are known, and unless the requirement itself is a definite one. I make this statement upon the basis of certain facts that I have collected in the past year.

The University of Cincinnati demands for entrance to its college of medicine one year of specified work in subjects which are generally conceded to be advisable, if not necessary, premedical subjects; namely, physics, chemistry, biology and modern language. At the University of Cincinnati, a year in these subjects means a certain amount of ground covered, in a certain amount of time, *i. e.*, three lecture periods (hour periods), and two three-hour laboratory periods, per week. The admission committee of the college of medicine, composed of the heads of the departments of chemistry, anatomy and pathology, have insisted that students coming from other colleges should present a *working* knowledge in physics, chemistry and biology equal to that demanded of University of Cincinnati premedical students. In the past year or so a few students have been refused admission by our admission committee, in spite of the fact that they had had a college year of physics, chemistry and biology, but had had courses in these subjects which could not reasonably be expected to produce the results that we demanded, or which did not produce these results, as proved by practical, oral, tests. Such students, however, had no difficulty in entering colleges whose announcements place them in the first group of Mr. Flexner. Apparently it is sometimes true that a one-year standard is a higher one than a two-year standard. It makes a great deal of difference whether a school lives up to a standard of efficiency, or a standard of prose (or poetic terms).

With regard to the "visible time" for research, I have no fault to find with Mr. Drinker, because in spite of everything he reaches a conclusion that appeals to me, but "visible time" in a schedule means nothing. If there is no "visible time" it may mean that the schedule has been arranged to suit the students who have just met the requirements, and that, so to speak, "invisible" time is a plenty for those who have more than met such requirements. But even aside—even admitting that all the students just meet the requirement—one needn't treat them all alike. As a matter of fact, it were well to try to treat

all differently. It is interest and enthusiasm we are after in medicine—not the dead routine of a schedule. We need very badly pedagogic vitality. One man may make, or be able to make, twice the progress of another in a certain subject. Why tie him to the class schedule? Why not take him into your own laboratory, for his class periods, give him an assignment of special work, and talk it all over with him. It is a stimulus to students and teachers. It makes for progress in the student, not for stagnation. It widens his perspective, and not infrequently wakes the teacher. A schedule is made for the general mediocrity, and in its planning visibility is a prime necessity.

PAUL G. WOOLLEY,  
Dean

COLLEGE OF MEDICINE,  
UNIVERSITY OF CINCINNATI

#### A PROPOSAL FOR THE CONTROL OF CERTAIN MOSQUITOES

WITH the discovery that a number of diseases are transmitted solely by certain mosquitoes the control of these insects has become an important problem. But for successful control work exact knowledge of the species involved and of their habits is essential. Until a decade ago Réaumur's admirable presentation of the life history of the common house mosquito (*Culex pipiens* L.) has been almost universally considered applicable to mosquitoes in general. Nothing was known of the specialization of habits in the different species and it was generally supposed that in temperate regions all mosquitoes hibernated in the adult female condition, to deposit eggs and start a new generation with the return of warm weather. Students of the group now know that there is great diversification of habits and that the old generalizations apply to but a very small proportion of the many species of mosquitoes. Nevertheless, the old ideas persist with many and are still disseminated in well-meant attempts to popularize the subject. One often encounters recommendations for mosquito-control based upon these old ideas and leading to failure and useless expenditure.

The greatest misconception is that swamps and bodies of stagnant water in general continue to produce mosquitoes in quantities throughout the warm months and that to reduce mosquitoes it is only necessary to oil or petrolize such places at sufficiently frequent intervals. In fact the bulk of the mosquito population of our northern woods and swamps (and this is true of Eurasia as well as of North America) is derived from larvæ which develop in the snow-water of early spring. During a short period all the lesser bodies of water swarm with mosquito-larvæ, to shortly become, for the remainder of the season, practically barren. The larvæ hatch from eggs which were deposited the previous summer on leaves or rubbish in depressions of the ground. There is but a single brood and the larval period is short; the female imagoes are long-lived (weeks and even months) and the egg-stage lasts through the winter to the following spring.

The species of mosquito which conform to the old idea, hibernating as female imagoes and producing a series of generations during warm weather, are, in temperate regions, few in number, and their control is comparatively a simple matter. It is true that in villages, towns and cities even in the northern states these *Culex* mosquitoes will breed in tin cans and bottles on waste lots, in cesspools, rain-water tanks, rainwater barrels and other receptacles, and cause much annoyance. A community wishing to rid itself of such mosquitoes must carry on a warfare directed against these particular mosquitoes.

The species hibernating as eggs and developing in early spring (mostly belonging to the genus *Aedes*, sense of Dyar and Knab) are, on the contrary, numerous in species and individuals, and under suitable conditions very annoying. Their control, through destruction of the larvæ, is a difficult matter. Petrolization, the method most recommended, must be carried out at just the right time. As the larvæ occur in practically all the numerous pools of snow-water scattered through woods and fields, operations will have to be very extensive to bring appreciable results. More-

over, in exposed places the wind is sure to drive the film of oil to one side and make it more or less ineffectual. It therefore appears that oiling for the control of these mosquitoes is not practical. Drainage, in many cases, can not be considered on account of the numerous small pools in which the larvæ occur.

The difficulty apparently has been solved in a recent suggestion by Dr. Adolf Eysell.<sup>1</sup> Discussing a recent pamphlet on mosquitoes by P. Sack, he criticizes the antiquated views and states that in Germany only three species of mosquitoes, *Culex pipiens*, *Culiseta annulatus* and *Anopheles maculipennis*, hibernate as imagos and that these are distinctly house-mosquitoes. All the other species, including two of *Anopheles*, are "wild" and hibernate in the egg or larva state. For the control of those hibernating as eggs Eysell suggests an easy method which should prove effective. It is the removal and burning, late in the autumn, of the old dead leaves and plant debris from the dried-out pools in which the larvæ would later appear. He further suggests that when it is inadvisable or impracticable to burn the egg-bearing leaves they be stacked on higher ground in such a way that they can not be carried back into the depressions by wind or rain. The latter method appears less effectual to the writer on account of the difficulty, at least in many localities, of finding permanently dry spots for such plant-rubbish. When one considers the very small amount of water that is necessary for the development of mosquitoes (the writer has found larvæ and pupæ in puddles less than an inch deep on practically level ground) and the possibility of heavy rains hatching the eggs and carrying away the young larvæ, this method seems less promising. The burning of the accumulations of leaves and rubbish from depressions of the ground, however, should give the best results. It is to be hoped that some one in a locality with well-determined mosquito conditions will give this method a fair trial.

FREDERICK KNAB

BUREAU OF ENTOMOLOGY

<sup>1</sup> *Entomol. Mitteilungen*, Vol. I., No. 11, November, 1912, p. 366.

### SCIENTIFIC BOOKS

*Comparative Anatomy of Vertebrates.* By J. S. KINGSLEY, Professor of Biology in Tufts College. Philadelphia, P. Blakiston's Son & Co. 1912. Pp. 401.

The author's purpose in writing this text-book, as stated in the preface, is to present a volume of moderate size which may serve as a framework around which the facts learned by the student in laboratory work in vertebrate anatomy may be grouped so that their bearings may be readily recognized and a broad conception of vertebrate structure may be obtained. "In order that this may be realized embryology is made the basis, the various structures being traced from the undifferentiated egg into the adult condition." "There has been no attempt to describe the structure of any species in detail, but rather to outline the general morphology of all vertebrates."

The task of preparing a text-book of this kind limited to a volume of moderate size is extremely difficult. Morphology, unlike physiology, or unlike chemistry or physics, lends itself to relatively few broad generalizations that may be stated without reserve. It deals essentially with data concerning the structure of a vast number of individuals in the adult condition and their development. While organisms are more or less readily classed into various broad and narrow groups according to the details of their structure and the genetic relationship of organisms, on the whole, may be most readily deduced from structural resemblances, nevertheless it remains true that living things are essentially individualistic in the character of their organic structure. Generalizations concerned with the structure of the tissues are much broader than those concerned with gross organic structure. The relatively simple conditions characteristic of the early stages in embryonic development also lend themselves to comparatively broad generalizations. The author, therefore, does well to devote rather more attention to the histological and embryological aspects of the subject than is customary in text-books of this character.

The introduction deals principally with the broader aspects of vertebrate embryology and histology. There then follow accounts of the integument, the skeleton, the coelom, the muscular system, the nervous system, the sense organs, the digestive organs, the respiratory organs, the organs of circulation, the urogenital system, the fetal envelopes and the adrenal organs. A bibliography of the more accessible books and monographs dealing with the subjects treated, and a list of definitions of systematic names used in the text precede the index. The figures used to illustrate the text are, in large part, original.

It would probably be impossible for an author in a text-book of this size to condense biological generalizations in a manner wholly satisfactory at all times to other students of the subject. Thus, for instance, in describing the neuron Kingsley states that "the processes are physiologically divisible into afferent and efferent tracts, the body of the cell being the place for the regulation and correlation of the impulses and, apparently, in many cells for the inauguration of new impulses." Most neurologists would be inclined to consider the primary function of the cell body to be the regulation of the nutrition of the neuron. Kingsley does not seem to discriminate in the text between "dendrites" and "telodendrons." It is quite certain that the corium is not derived wholly from the somatic wall of the myotomes, as is implied in Kingsley's description of the development of the integument. In describing the articulations of the endoskeleton Kingsley states that "the bones may be so articulated that one can move on the other (diarthrosis), or there may be no motion possible (synarthrosis), each with several varieties." These brief descriptions of the two main types of joints are certainly not happily chosen. In describing entochondrostosis the author states that the cartilage becomes broken down in the interior, some of the cells becoming modified into osteoblasts. This is not the generally accepted view of the process at present. The notochord is certainly not of entodermal origin throughout the vertebrates. In describing the

vertebræ the author would have done well to state what becomes of the costal elements of the lumbar and sacral vertebræ. While the use of the term "anterior" to mean the head-end of the animal and the term "posterior" to mean the tail-end of the animal is satisfactory for all vertebrates, including man, it is a mistake to translate "anterior" into "front," and "posterior" into "behind," as may be seen from the following description: "In man it (the sternum) consists of three parts, a manubrium in front, a middle piece, and a xiphoid (ensiform) process behind." The description of the origin of the muscles of the diaphragm in mammals is incorrect and nothing is stated about the interesting nature of the innervation of the diaphragm. The sternocleidomastoid muscle should not be placed in the same group with the scalene and intercostal muscles. The author's division of the muscles of the limb into intrinsic and extrinsic does not seem to aid in giving a clear picture of the morphology of the limb musculature. The Vidian nerve does not represent a distinct sympathetic trunk. The width between the bases of the pillar cells in the organ of Corti increases from the base to the apex of the cochlea instead of decreasing, as described by the author. It is incorrect to describe the duodenum as that part of the alimentary canal which extends from the pylorus to the entrance of the bile duct. The text description of the embryonic origin of the thyroid is unsatisfactory, and the parathyroid glands are not mentioned. The epiglottis does not fold back toward the glottis during deglutition. Hemoglobin does not combine with carbon dioxide. The origin of most of the larger blood vessels in the body from embryonic vascular plexuses, which forms so striking a feature of the development of the circulatory system, is not clearly described by the author, but, on the other hand, the doubtful theory of the development of blood vessels as remnants of the segmentation-cavity has a couple of paragraphs devoted to it.

The proof-reading appears at times to have been somewhat careless. Fig. 22 is upside

down. The lettering on the coracoid process, Fig. 108, is incorrect. The olecranon process is described on page 120 as extended beyond the elbow joint to the attachment of the extensor muscles of the lower limb. The lettering of the pancreatic duct in Fig. 242 does not correspond with that of the legend.

Kingsley's book lends itself for comparison most readily with Wiedersheim's "Comparative Anatomy of Vertebrates," especially with the English edition edited by W. N. Parker. The general field covered is similar, although there are about one hundred more pages in Wiedersheim. Wiedersheim has the advantage of having been extensively used and revised since the first edition in 1882, so that the weaker parts have been gradually strengthened and the cruder errors eliminated. On the other hand, a text-book revised from year to year over so long a period may display many points of view less satisfactorily than a text-book newly written. The relatively greater attention given by Kingsley to histology and embryology is a distinct advantage and might be satisfactorily carried out further. On the other hand, both illustrations and text descriptions are, in many phases, clearer in Wiedersheim's than in Kingsley's text-book. The bibliography given in Wiedersheim is far more extensive, but, on the other hand, that given in Kingsley is, on the whole, well selected, and, possibly, for beginning students, by being less extensive may be more useful.

C. R. BARDEEN

THE UNIVERSITY OF WISCONSIN

*The Growth of Groups in the Animal Kingdom.* By R. E. LLOYD, M.B., D.Sc. London, Longmans, Green and Co. 1912. Pp. 185, with two colored plates. Price \$1.75 net.

"The aim of this small book is to lessen the belief in natural selection as a creative agency." "The word group appears in the title of this work and will be found throughout the text. It is used in place of the more usual terms species, sub-species and variety." "A group is a number of individuals (more than one), each possessing some particular

character or characters which are chosen arbitrarily as the distinguishing marks of that group." "From a practical point of view species are those groups which have been described as such."

Although the idea expressed in the last quoted sentence is by no means novel, it is interesting as illustrative of a change which seems to be coming over biology. Many will still dispute both the author's and the reviewer's statements. However, it is indisputable that not only is the "method of the origin of species an open question," but it is more than ever a question as to what a species is if it be more than a mere convention. It is curious that so many well-informed taxonomists accept evolution as a principle, but stick to the independent creation of species in practise. The "splitters" are unconsciously breaking down this practise, for species are being based on fewer and less important characters than ever. The process is a *reductio ad absurdum* and can not help but end in the definition of species just given. The author seems justified in saying: "If it is true that our conception of a species has changed it is necessary to modify our opinion as to the origin of a species. Some of those who are interested in the origin of species do not know how small are the differential gaps which separate our modern species."

About half of the book is devoted to an account of the different sorts of rats found among about 100,000 killed during the work against the plague in India. Some of these have already received names differentiating them from *Mus rattus*. Other have not. As a contribution to our knowledge of the amount of readily appreciable variation in a feral "group," this work is valuable. It is the only important original thing the book contains and is followed by a lengthy résumé of some of Tower's work upon *Leptinotarsa*. Unfortunately the author did not subject the rat "mutants" to experimental tests, nor does he refer to the breeding work already done with rats. The facts collected are believed to be in harmony with that part of the mutation theory which asserts that the attributes of

organisms consist of distinct, separate and independent units.

As a practical application of the theory he suggests that many forms of insanity are merely the distinguishing characteristics of human mutants. "*Dementia præcox* is neither fatal in itself, nor curable. Were it either we could not of course regard it as the expression of a character or group of characters, or compare its victims to mutants." In addition to the punctuation, one might be inclined to object to the implication that the possessor of a new character can not be compared to a mutant if the new character be fatal to its possessor.

The author assures us that the philosophical conclusions in the last chapter were reached before reading Bergson. There is something of a similarity—at least as to the quality of indefiniteness and the appeal to the unknowable. The concluding sentence is a warning that the belief in natural selection encourages a belief in "the right of the spirit of competition which is daily invoked in order to smother those altruistic feelings that are an important part of the human mind."

The discussion of "species" is interesting and the important facts concerning the rats are well presented.

FRANK E. LUTZ

*The Flowing Road; Adventuring on the Great Rivers of South America.* By CASPAR WHITNEY. Philadelphia and London, J. B. Lippincott Company. 1912. Pp. 319. Illustrated.

The title of this book leads one to look for something in the way of scientific results, but the author disclaims any scientific mission (173), and it is only by much courtesy that it can be regarded as scientific in any sense. But in spite of this, it is a book full of interest for every one who knows, or wishes to know, about the ups and downs of canoe travel in the thinly populated and little-known regions of the upper Rio Negro, or for the matter of that, on any of the rivers that empty into the Amazon.

The author's preface would lead one to sup-

pose that Humboldt and Wallace were almost the only explorers of the upper Rio Negro region, and he fails to mention Dr. Richard Spruce, who lived and labored there longer than all the others put together. Humboldt was on the upper Orinoco only two months—April and May, 1800; Wallace went up the Rio Negro in August, 1850, and returned to Manaus May 17, 1852; Spruce lived in that region from December, 1851, to December, 1854—just three years. The account of Spruce's residence is given in the "Notes of a Botanist on the Amazon and Andes by Richard Spruce, London, 1908," and his results are published in more than fifty scientific papers, mostly on South American botany and natural history, brought out by the learned societies of England and Scotland.

Likewise no mention is made of the almost incredible explorations of Henri A. Coudreau in the Amazon region, including a trip up the Uaupés in 1884, and described in his "Voyage a travers les Guyanes et l'Amazonie," Paris, 1887.

This, however, has but little to do with the book itself. In spite of the almost deadly sameness of the region and of the daily life, the author finds something or much of interest and beauty everywhere, and under all circumstances. And it is a great pleasure to follow a man who likes to see the animals without wanting to shoot them all to pieces, who accepts the weather and the fortunes of travel as they come along without complaint, who has human sympathy with the people, however humble, and who doesn't want to impose his ways of doing things upon every one he meets. This wholesome attitude of the author, even if there were nothing else in it, makes the book richly worthy of the attention of naturalists and of others who would travel in the country treated of.

Another peculiarity of the book is that the author doesn't begin in New York or London with the details of how many trunks, boxes and packages he had and what each one contained; he doesn't describe the voyage out, and the steamer, and the service, and the flying fish, and the southern cross and all the

rest of it. With a brief sketch of the lower Amazon and lower Rio Negro, he begins his story of the trip at Santa Isabel nearly half way up the Rio Negro. With the same promptness, the best of the book—the part which treats of the trip across from Santa Isabel to Ciudad Bolívar on the lower Orinoco—comes to a living end at 4:30 A.M., after his long voyage, when “my canoe grated the sloping bank of Ciudad Bolívar, and I stood upon the beach, bare-legged to the thighs, looking, no doubt, in tattered shirt, like a derelict cast up by the sea.”

The remainder of the book is only remotely related to this first and most important part of it, but it is all interesting. Chapter XIX., however, at the end, relates to outfitting for travel in tropical regions and is the best thing of the sort we have seen; and in the opinion of the reviewer the best things among the many valuable suggestions are these: go light, eat what the natives eat, sleep in a hammock, avoid liquor, don't scratch insect bites. He forgot to add: “Learn the language of the people.”

This last point suggests that the book contains a few errors in Portuguese which a little care might have avoided. Such are “batelão” for batelão, “Rio Janeiro” (74, etc.) instead of Rio de Janeiro, “cachaca,” rum, for cachaca (43, etc.), “igarapee” for igarapé (47-49), “madrugar” for madrugada (84).

There are also a few erroneous statements in regard to plants which it is hoped may be corrected in future editions: that *farinha de mandioca* is made from the root of a yucca (33); that *piassava* is a “fiber parasite” of a palm (118); that Panama hats are made of “the fine and enduring straw” of a palm. As a matter of fact the *piassava* fiber is from the edges of the petioles of the palm, and is in no sense a parasite, while the straw of which the hats are made are from the leaves of a species of screwpine.

On the other hand he does well to correct the impression, so popular in temperate regions, that South America swarms with snakes; and he justly discredits the exagger-

ated stories to be heard all over South America of the numbers and dangers of the jaguars. He does well also to mention the everlasting stumbling blocks placed in the road of the foreign wayfarer (213)—an item the foreigner should be prepared for before he begins his wayfaring.

In his preface Mr. Whitney speaks rather lightly of the fevers and intimates that they belong to the category of robbers and reptiles (4). Having come safely out of some of the most unhealthful parts of South America, it is natural enough for him to think lightly of the fevers. But when he takes a serious view of the possibilities of the region about San Fernando he finds himself confronted by “the insect host and the fever—a forbidding pair” (111).

The writer is in entire sympathy with this author's general cheerful attitude in regard to the people and their ways and the country in general, but he thinks it due to those who are likely to go there to call attention to the abundant evidences of fevers and of their sad work as set forth in “Recollections of an Ill-fated Expedition,” etc., by N. B. Craig, Philadelphia, 1907, and indeed in the experience of every one who has lived long in that country.

It is a pity that the book is not supplied with better maps. J. C. BRANNER

#### MINERALOGY IN JAPAN

THE valuable Japanese periodical issued in Tokyo by T. Wada, under the German title “Beiträge zur Mineralogie von Japan,” offers many interesting articles in its fourth number (June, 1912), all of them being written in English by their Japanese authors. Among them we note an account of the fall of meteorites which took place July 24, 1909, in the districts of Mugi and Yamagata, province of Mino.<sup>1</sup> The writer, Tetsugoro Wakimizu, states he was at the time in the town of Ogaki, about twenty miles distant, when he heard a sound like the report of a cannon, accom-

<sup>1</sup>“Beiträge zur Mineralogie von Japan,” ed. by T. Wada, No. 4, pp. 145-150, 1 pl., 1 map; Tokyo, June, 1912.

panied by quite noticeable vibration; indeed, the noise was heard over an area of nearly 4,400 square miles. The ground on which this, the most remarkable fall of meteorites noted in Japan, took place, was of elliptical outline, measuring about  $7\frac{1}{2}$  miles in length and 3 miles in width. The writer carefully examined 24 of the 25 stones gathered from this field, and he estimates that probably five times as many are still lying in the fields and between the hills. He notes that fewer but larger stones came from the northern part of the territory than from the southern part; the largest weighs a trifle over 89 pounds (1,076.8 *monme* = 40,389.7 grams). All these stones, probably fragments of a single original mass, are a white chondrite with some minute grains of nickel iron and iron sulphide in the interstices between the stone components. Oxidization was very rapid. These meteorites are holocrystalline, consisting of prismatic crystals and grains of olivine and bronzite. The primary crust, from  $\frac{1}{8}$  to  $\frac{1}{2}$  mm. in thickness, is formed of oxidized grains of nickel iron and iron sulphide.

The following gives the results of an analysis of one of these meteorites (Hachiman) by Sugiura in the Imperial Geological Survey of Japan:

H <sub>2</sub> O .....	0.334
SiO <sub>2</sub> .....	41.012
P <sub>2</sub> O <sub>5</sub> .....	0.458
TiO <sub>2</sub> .....	0.416
F <sub>2</sub> O <sub>3</sub> .....	5.470
Fe .....	20.583
Ni .....	0.183
Mn .....	0.910
CaO .....	2.768
MgO .....	24.707
S .....	2.185
SO <sub>2</sub> .....	0.201
C .....	trace
Total .....	99.227

The meteoric iron "Okano" is also described by Tadasu Hiki, and figured on two plates.<sup>2</sup>

The most important article in the number

<sup>2</sup> *Loc. cit.*, pp. 142-144; plates VII. and VIII.

is an account of the mineral resources of the Island of Formosa, ceded to Japan after the war with China in 1895.<sup>3</sup> Gold is present there in fair quantity, the principal mines being near Kiirun. The Chinese carried on gold mining in Formosa as early as 1669, and gold sand was noted on the east coast by the Portuguese in the fourteenth century. The gold deposits near Kiirun were discovered in 1890 by a Chinese who came across gold sand while work was in progress on a bridge over the Kiirun River. The value of the gold obtained in Formosa by the Japanese in 1910 is stated to be 2,119,981 yen or over a million dollars; of this 63,964 yen represented the worth of the placer gold.

Gem minerals are represented to a somewhat limited extent. Chalcedony, white and red-banded, has been found in volcanic rocks at Kappansha and in the Tartō district, and in basaltic cavities in the Hōko-tō group; red, yellow, brown, blue, green and other colors are represented; some specimens here are large enough to be polished for ornamental use. Associated with these latter chalcedonies, attractive semi-transparent opals have been found, sometimes blue and occasionally gray. Minute crystals of zircon occur in the gold placers of the Kiirun River. Red garnet appears in fragments with gold sand and magnetite on the coast of Dainan-ō, and minute garnet crystals occur embedded in crystalline schist at Basshi-sho.

Other articles in this number are: "On the twelve dimples of the aragonite balls, found in Taira, Shinano," by Nobuyo Fukichi, pp. 133-138; "On a Small Sinter-cone Formed by a Geyser at Obama, Hizen," by Denzō Sato, pp. 139-141, pl.; "*Kurokō*, or the Black Ore," by Takeshi Hirabayashi, pp. 151-156. Many interesting data are also grouped under the general heading, "Kleinere Mitteilungen."

A concession for pearl-fishing in the South Ussuri district of western Siberia was recently accorded by the Russian government to A. D. Popoff, of Vladivostok. This field is now being exploited with some success with the aid

<sup>3</sup> Yōhachirō Okamoto, "Minerals of Taiwan (Formosa)," *loc. cit.*, pp. 157-188.

of trained divers from European Russia, and the prospects for a satisfactory yield of pearls are considered to be good.\*

GEO. F. KUNZ

### SPECIAL ARTICLES

#### THE DOCOPHORI OF THE OWLS

EXACTLY a dozen species of *Docophorus* (genus of Mallophagan parasites) have been described from the owls (*Strigidae*). I think the number is about double what it ought to be. The species center about three well-known and well-differentiated types, represented by the long-established species, *D. rostratus* Nitzsch, *D. cursor* Nitzsch and *D. ceblebrachys* Nitzsch. The name of Nitzsch means that these three species were described about a hundred years ago and were based on specimens derived from European birds. All of these species have since been taken from North American owls, as well as from owl hosts from other parts of the world.

The three species differ markedly from each other in various characters, the most quickly recognizable of which are the shape and markings of the head. In *rostratus* the clypeal portion of the head is drawn out and narrow in front, in *cursor* it is shorter and broader, and in *ceblebrachys* it is still shorter and broader, so that the head is a sort of broad, solid, bull's head. The species might well have been named *taurocephalus*, a name used later by me for another *Docophorus*.

Of the nine other so-called species of owl *Docophori* three have been described from American specimens, viz., *D. syrnii* by Packard from *Strix varia varia* from Ohio; *D. bubonis* by Osborn from *Bubo virginianus* from Pennsylvania, and *D. speotyti*, also by Osborn, from *Speotyto cunicularia hypogæa* from Nebraska and Colorado. *D. syrnii* Packard is unrecognizable. It does not count. Professor Osborn's two species do count, of course. They belong to the *cursor* type of owl *Docophori* and are very partial, indeed, to this type, for they imitate their European

model pretty closely. However, Professor Osborn's specimens are different from Nitzsch's. But that is a conspicuous thing about the Mallophaga. The individuals of the same species, when they are taken from different host individuals, reveal easily perceived differences. It is a condition that comes about, probably, through the unusual isolation of the separate groups of individuals that compose the species. Each group, which is at bottom a family group, and represents a family strain, is more or less effectively marooned on an animated island, which is the body of its individual bird host. And hence the variations of each family strain are preserved and accentuated by the necessary inbreeding due to this isolation.

Thus while Professor Osborn's *cursor*-like species are different, they are not very different, and the same is true of several other species of owl *Docophori* representing not only the *cursor* type but the *ceblebrachys* and the *rostratus* type.

I have just received from Professor Cockerell several specimens of *Docophorus* from *Asio flammea* (collected at Boulder, Colorado) and in attempting to determine them I am interested to discover that if I follow tradition I shall have to add another species of *Docophorus* to the list for the owls, which would make the thirteenth! This makes me hesitate. What I believe ought to be done is to let these new specimens unite some friendly but now separated species, instead of compelling them to make the situation more intolerable. For to recognize thirteen species of one Mallophagan genus from thirteen species of owls—for that happens to be the exact number of owl species from which *Docophori* have been taken—and four of them from a single owl kind, would be unnatural, and also most inviting of ill luck! I am sure of the unnaturalness from my knowledge of the host distribution of the Mallophaga. The trouble is that the isolation of the *Docophorus* (and other Mallophagan) individuals on owls is even more effective than on most other birds, for owls are peculiarly non-gregarious and

\*Report of Consul John F. Jewell, of Vladivostok.

offer unusually little opportunity for the passage from host to host of the wingless parasites. There is thus all too little cross-breeding, and family idiosyncrasies get all too easily preserved and made the basis of species separation. What I propose to do then, in a forthcoming systematic paper on the Mallophaga, is to reduce the number of species of owl *Docophori* and of some other similarly expanded groups. This present note is simply notice to that effect, with a suggestion of the biological reason why.

VERNON L. KELLOGG

STANFORD UNIVERSITY

#### ENOOTHERA AND CLIMATE

In their interesting account of a recent visit to Bartram's locality for *Enothera grandiflora*, at Dixie Landing on the Alabama River, Professor de Vries and Mr. Bartlett<sup>1</sup> say:

Neither *Æ. grandiflora* nor *Æ. Tracyi* has heretofore been known as other than annual, and the abundance of rosettes which would obviously not flower this season was therefore a point of great interest.

In growing *Æ. grandiflora* and many other *Enotheras* under a variety of climatic conditions, I have been greatly struck by the different ways in which they respond, both as regards the annual or biennial habit and the time of flowering in a given season. Seeds of a series of *Enothera grandiflora* forms from Birkenhead, England, which I planted in a tropical greenhouse at the University of Chicago in July, 1907,<sup>2</sup> were grown under tropical conditions, the plants remaining rosettes throughout the winter and flowering in May, 1908. *Æ. Lamarckiana* forms treated in the same manner nearly all remained rosettes indefinitely, *i. e.*, for about twenty-two months, until the experiments were suspended. This difference in behavior I at-

tributed to the fact that *Æ. grandiflora* is adapted to a more southern climate than *Æ. Lamarckiana*. In 1909 I observed typical rosettes of *Æ. grandiflora* growing in mid-summer (probably as escapes) in uncultivated land of the Missouri Botanical Garden. Hence in that climate also the plant is biennial. From these and related facts, together with the observations of de Vries and Bartlett, it is probable that all the *Enotheras* of this group are biennial in their native localities.

When grown from seeds planted in the greenhouse in January or March, *Æ. grandiflora* often omits entirely the rosette stage, beginning to form a stalk when quite a young seedling. In my cultures under these conditions the characteristic leaf-type of the mature rosette is always omitted. The plant, therefore, unlike the *Æ. Lamarckiana* forms, becomes annual by shortening its life cycle.

Plants of *Æ. grandiflora* grown from seeds from Dixie Landing behaved in still a different way in the English climate this year. Seeds were sown in the greenhouse in January, and the young seedlings planted out in the end of May. They formed very imperfect rosettes but, though stem-formation began early and they grew luxuriantly, yet they failed almost completely to come into bloom, only two plants out of two hundred and twenty-one producing any flowers.

Incidentally it may be mentioned that, as I have pointed out elsewhere,<sup>3</sup> *Æ. grandiflora* occurred in the region of Carolina and Virginia as late as 1821 (Barton's "Flora of North America," Vol. I, plate 6). It would be worth careful search to discover if individuals do not still survive in this region, for that was undoubtedly the source of the large-flowered *Enothera* described by Ray in the "Historia Plantarum," 1686, and which must have belonged to a race either of *Æ. grandiflora* or of *Æ. Lamarckiana*.

Seeds which I obtained from Birmingham,

<sup>1</sup>De Vries, Hugo, and Bartlett, H. H., "The Evening Primroses of Dixie Landing, Alabama," *Science*, N. S., 36: 599-601, 1912.

<sup>2</sup>See Gates, R. R., "An Onagraceous Stem without Internodes," *New Phytologist*, 11: 50-53, pls. 2-3, 1912.

<sup>3</sup>Gates, R. R., "Early Historical-botanical Records of the *Enotheras*," *Proc. Iowa Acad. Sci.*, 1910, p. 108.

Alabama, through the kindness of Mr. Robert A. Love, yielded a race which behaved in the same way, and which evidently belongs to the *Æ. Tracyi* described by Bartlett.<sup>4</sup> The plants, which were grown at the John Innes Horticultural Institution this year, numbering 173, were very uniform and agreed in general with Bartlett's description. They were very tall and stout, much more so than *Æ. grandiflora*, and several plants showed small buds at the end of September. Certain other facts in this connection are referred to in a paper now in press in the *Transactions* of the Linnean Society.

In growing scores of wild races belonging to the species *Æ. biennis*, *Æ. muricata*, *Æ. grandiflora*, *Æ. argillicola*, *Æ. Hookeri* and others from various parts of North America, in the climate of England during the past summer, I have been greatly impressed by the constancy and the peculiarity of each race as regards such physiological characters as the strength of the biennial habit, and the time of blooming. The differences in these respects are quite as marked and constant as any morphological characters can be, and in hybrids they are frequently intermediate. Evidently each race is closely adapted to the conditions of the growing season in its own native locality; and within certain limits it is possible to predict what the behavior of a race will be when one knows the latitude and climatic conditions from which it came. The elucidation of the origin of these racial climatic adaptations in *Enothera* is a most interesting evolutionary problem.

#### INHERITANCE OF THE RUSSET SKIN IN THE PEAR

The russet skin occurs commonly in the pear and it is found in amounts varying from 0 per cent. to 100 per cent. In Ragan's "Nomenclature of the Pear"<sup>1</sup> are described

<sup>4</sup>Bartlett, H. H., "Systematic Studies on *Enothera*. I. *Enothera Tracyi* sp. nov.," *Rhodora*, 13: 209-211, pl. 93, 1911.

<sup>1</sup>U. S. Dept. Agric., B. P. I. Bull. 126, 1908.

547 varieties having no russet, and 772 varieties having a very light to a solid russet covering. In the latter class only 16 are given as simply "russet"; however, several others, as the Bosc, should come under this head. The low number of russet individuals indicates that the russetting is recessive to the smooth-skinned condition, and that many of the partially russeted and smooth-skinned pears must be heterozygous—the dominance of the smooth-skinned condition being frequently incomplete.

The results obtained at the New York Agricultural Experiment Station, Geneva, New York, support such a postulation. In a cross between Kieffer ♀ and Elizabeth ♂, both parents having smooth skins, were obtained two russeted and ten smooth-skinned seedlings. This population is too few in number to allow one to draw definite conclusions; nevertheless, it approaches closely a simple 3:1 Mendelian segregation. In a cross between Bosc ♀ and Kieffer ♂, the ♀ parent having a russet skin and the ♂ parent carrying the russet condition as a recessive<sup>2</sup>, there were produced five seedlings—two of which were smooth-skinned and three russeted. The progeny of this latter cross approximate a 1:1 Mendelian ratio, viz., one individual is homozygous to the smooth-skinned condition and one individual is heterozygous to russetting. As a Russet Bartlett of unknown origin, differing from the normal Bartlett in no character except the skin—even in the self-sterility of the blossoms—is growing on the experiment station grounds, it is reasonable to suppose that the russet condition is due to a loss of a determining factor, for the loss of a character is much more common than the addition of a new one.

EXPERIMENT STATION,  
GENEVA, N. Y.

#### SOCIETIES AND ACADEMIES

ACADEMY OF SCIENCE, ST. LOUIS

A MEETING of the Academy of Science of St. Louis was held at the academy building, Monday, November 18, President Englar in the chair.

Professor James F. Abbott, of Washington University, addressed the academy on "Permeability of Animal Membranes," dealing particularly with some experiments conducted during the summer on fiddler crabs.

Dr. C. H. Turner, of the Sumner High School, gave a short talk on "The History of an Orphan Colony of a Paper-making Wasp"; and Dr. H. M. Whelpley spoke on "Indian Miniature Axes and Celts," illustrating his remarks with numerous interesting examples.

Professor F. E. Nipher, of Washington University, presented some results of his experiments on "The After Effects in an Aluminum Wire used in Electric Discharge."

Since making a communication to the Academy of Science of St. Louis on November 4, experiments have been made in the study of the creeping of an aluminum wire through which a rarefaction wave is sent.

When a fresh wire is used, the wire creeps in a direction opposite to that of the corpuscular displacement.

After the discharges from a condenser of large capacity have passed through the wire for fifteen or twenty minutes the position of the wire is reversed; no other change being made, the wire creeps in the opposite direction in space. This has been repeated many times.

On the other hand, if the polarity of the influence machine is reversed the wire creeps in the same direction in space.

The end of the wire which is in advance in the motion of the first case is in advance in the two subsequent cases.

In the two latter cases the wire creeps toward the positive terminal. The discharge terminals at the wire were in the form of rings of large copper wire, which closely encircled the aluminum wire. The long spark was in the conductor leading to the positive terminal of the machine, about ten feet distant. Some preliminary experiments seem to indicate that this after-effect can not only be eliminated, but that it can be reversed.

Such effects have not been observed in copper wires, but it is possible that a decrease in the sensitiveness of response of the wire was due to this cause, and not to frictional contact in the grooved supports, as had been supposed. It was at first thought that the effects described might be explained as differential end or point reactions between the ends of the wire and the air and other surrounding matter. The ends of the wire were, however, bent

downward, so that they point in a direction at right angles to that in which the wire creeps. Either end may be bent downward, the other pointing either in the direction of motion, or in the reverse direction, without affecting the direction in which the wire creeps, in any material way. This apparently eliminates end effects from any part in these very remarkable results, and it is entirely possible that some of the conclusions heretofore published may require modification.

It would not be surprising, in view of these results, to learn that the resistance of this wire depends upon the direction of flow of the current.

GEORGE T. MOORE,

Secretary

#### THE BOTANICAL SOCIETY OF WASHINGTON

THE 83d regular meeting of the society was held at the Cosmos Club November 12, 1912. The program included the following papers:

*A Portrait of Linnæus*: Dr. J. N. ROSE.

Dr. Rose exhibited an engraved portrait of Linnæus which had recently been presented to the Smithsonian Institution by Captain John Donnell Smith, of Baltimore, who had previously given to that Institution his magnificent herbarium and library. This portrait is one rarely seen in this country, being a mezzotint of one of the earliest portraits of Linnæus, the original being a replica of Hoffman's famous picture showing Linnæus in Lapland dress, of which the original is now the property of the Clifford family. This replica was known to have been in the possession of one Thornton as late as 1811; but its whereabouts now is not known.

Dr. Rose also called attention to the large collection of portraits of Linnæus in the possession of the Linnean Society, and also to the work of Tycho Tullberg, "Linneporträtt," a quarto volume of 185 pages with 25 portrait plates.

"*Rough-bark*," *Disease of the Yellow Newtown Pippin*: Mr. JOHN W. ROBERTS.

*Botanizing in the Region of the Natural Bridges of Southeastern Utah*: Dr. P. A. RYDBERG (by invitation).

THE 84th regular meeting was held at the Cosmos Club on December 3, 1912. The program included the following papers:

*Summary of Studies of Glomerella* (with lantern): Dr. C. L. SHEAR.

*Probable Origin of Maize* (with lantern): Mr. G. N. COLLINS.

*The Effect of Lime on the Alkali Tolerance of Wheat Seedlings* (with lantern): Dr. J. A. LeCLERC and Mr. J. F. BREAZEALE.

C. L. SHEAR,  
*Corresponding Secretary*

#### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At the meeting of the society in the New National Museum on Tuesday afternoon, November 19, President George R. Stetson in the chair, Mr. James Mooney, of the Bureau of American Ethnology, lectured upon "The Gaelic Language of Ireland."

The lecturer outlined the history of the Keltic nations, of whom the Gael of Ireland and Scotland are a part, from their first acquaintance with the Greeks about six hundred years before Christ, down to the storming of Rome in 390 B.C.—the earliest authenticated date in Roman history—their alliance with Alexander the Great, their invasion of Asia Minor and colonization of Galatia in 278 B.C., and the final subjugation and Latinization of the continental Kelts by the Romans about the beginning of the Christian era.

Gaelic is the oldest living language in Europe, unless we except modern Greek, and it closely resembles Latin in many of its roots.

The Gaelic colonization of Ireland probably dated as far back as 1000 B.C. The island was known to the Greeks under a form of its native Gaelic name of Eire as early as four centuries before Christ. The ancient annals mention several earlier races or colonizations, the most important being the Firbolg, probably a part of the Belgæ of the continent. They continued to exist as a distinct people under their own chiefs up to the sixth century or later.

The alphabet of pre-Christian Ireland was the Ogam (Ogum), a system of straight lines or dots ranged along either side of a base line, and somewhat resembling a cross between the Morse alphabet and the cuneiform inscriptions. It was used chiefly for monumental inscriptions, and continued in use to some extent up to the tenth century. The modern Gaelic alphabet, consisting of seventeen letters, is an adaptation from the Roman.

Mention was made of some of the most ancient manuscripts, some of which have been already translated and others of which are now under translation by the Irish Texts Society. Under the Penal Laws, from 1691 until about 1800, the whole native population was practically debarred from

education. Under the so-called National School System, established in 1831, the national language continued to be proscribed, resulting in its rapid decline. The great famine of 1845-7 with the ensuing wholesale emigration reduced the Gaelic-speaking population by nearly one half within twenty years, the great majority of those remaining being entirely illiterate. In 1878 the first concession to the native language was made by the national schools. In 1893 the Gaelic League, under the presidency of Dr. Douglas Hyde, began an active propaganda for the restoration of the language to its proper status, with the result that it is now taught in 3,000 of the 8,000 governmental "national" schools, as well as in a large number of private and denominational schools, a whole flood of modern Gaelic literature covering every subject of intellectual interest is coming from the press, and the Gaelic language has been made an essential for matriculation in the new National University of Ireland beginning with 1913. Out of its own funds the league also maintains ten normal colleges for the training of teachers in the language, in several of which schools the entire course of instruction is through the Gaelic. The census just completed shows that Gaelic is still the home language of nearly 600,000 persons in Ireland above the age of three years.

Outside of Ireland the Gaelic speakers in Scotland, England, the United States, Canada and elsewhere probably number considerably over a million. Prince Edward Island and adjacent parts of Nova Scotia have a compact body of about 100,000, mostly descendants of emigrants from the Hebrides. In this country Gaelic instruction is now conducted in several universities and a translation of the Rubaiyat, in Gaelic language and type, was recently published in Chicago.

## Teachers

We have many books on our list which you would find most excellent as text-books for your classes. They are books that meet the needs of High Schools, Preparatory Schools, and general College work. They are up to date books—kept so by frequent revisions. They are written by teachers who *know* their subjects—and how to impart their knowledge to others. Are *your* classes using our books? We honestly believe you will find it worth your while to examine our list with a view to adopting such as meet your text-book needs. Read over the titles below.

**Economic Zoölogy.** By L. S. and M. C. DAUGHERTY. Part I: *Field and Laboratory Guide*. 12mo of 237 pages, interleaved. \$1.25 net. Part II: *Principles*. 12mo of 406 pages, illustrated. \$2.00 net. *Just ready.*

**Biology.** By JOSEPH McFARLAND, M.D. 12mo of 440 pages, illustrated. \$1.75 net.

**Veterinary Bacteriology.** By ROBERT E. BUCHANAN, Ph.D. Octavo of 516 pages, 214 illustrations. \$3.00 net.

**Veterinary Anatomy.** By SEPTIMUS SISSON, S.B., V.S. Octavo of 826 pages, 588 illustrations. \$7.00 net.

**General Bacteriology.** By EDWIN O. JORDAN, Ph.D. Octavo of 623 pages, illustrated. Cloth, \$3.00 net. *Third edition.*

**Bacteriologic Technic.** By J. W. H. EYRE, M.D. Octavo of 375 pages, with 170 illustrations. \$2.50 net.

**Laboratory Bacteriology.** By FREDERIC P. GORHAM, A.M. 12mo of 192 pages, illustrated. \$1.25 net.

**Personal Hygiene.** Edited by WALTER L. PYLE, M.D. Chapter by H. W. WILEY, M.D. 12mo of 515 pages, illustrated. \$1.50 net. *Fifth edition.*

**Personal Hygiene and Physical Training for Women.** By ANNA M. GALBRAITH, M.D. 12mo of 371 pages, illustrated. \$2.00 net.

**Exercise in Education and Medicine.** By R. TAIT MCKENZIE, M.D. Octavo of 406 pages, 346 illustrations. \$3.50 net.

**Nutritional Physiology.** By PERCY G. STILES, Ph.D. 12mo of 295 pages, illustrated. \$1.25 net. *Just ready.*

**Invertebrate Zoölogy.** By GILMAN A. DREW, Ph.D. 12mo of 201 pages. \$1.25 net.

**Physiology.** By WILLIAM H. HOWELL, M.D., Ph.D. Octavo of 1018 pages, illustrated. \$4.00 net. *Fourth edition.*

**Elements of Nutrition.** By GRAHAM LUSK, Ph.D. Octavo of 402 pages, illustrated. \$3.00 net. *Second edition.*

**Normal Histology and Organography.** By CHARLES HILL, M.D. 12mo of 468 pages, 337 illustrations. \$2.00 net. *Second edition.*

**Histology.** By A. A. BÖHM, M.D., M. VON DAVIDOFF, M.D., and G. CARL HUBER, M.D. Octavo of 528 pages, 337 illustrations. \$3.50 net. *Second edition.*

**Embryology.** By J. C. HEISLER, M.D. Octavo of 432 pages, 205 illustrations. \$3.00 net. *Third edition.*

**American Pocket Medical Dictionary.** Edited by W. A. NEWMAN DORLAND, M.D. 610 pages. \$1.00 net. *Seventh edition.*

**Immediate Cure of the Injured.** By ALBERT S. MORROW, M.D. Octavo of 360 pages, 242 illustrations. \$2.50 net. *Second edition.*

**Hygiene.** By D. H. BERGEY, M.D. Octavo of 555 pages, illustrated. \$3.00 net. *Fourth edition.*

W. B. SAUNDERS COMPANY

Philadelphia and London

# NEW MCGRAW-HILL BOOKS

## PHYSICS

### **PALMER—The Theory of Measurements**

By A. de FOREST PALMER, Ph.D.

Associate Professor of Physics in Brown University.

248 pp. with Tables and Diagrams. \$2.50 (10/6) net, postpaid.

A thorough discussion of the principles underlying the precision of measurements, and the development of suitable methods of measurement for special purposes.

### **NORTHROP—Methods of Measuring Electrical Resistance**

By EDWIN F. NORTHROP, Ph.D.

389 pp. Illus. \$4.00 (17s) net, postpaid. An authoritative treatise of value not only to physicists and teachers but to men in practice as well. It describes and gives methods, simple measurements, details of instruments, etc.

## CHEMISTRY

### **International Chemical Series**

HENRY P. TALBOT, Ph.D., Consulting Editor

The first volumes in this series have had a gratifying reception. Each has been adopted already in several institutions.

### **NORRIS—The Principles of Organic Chemistry**

By JAMES F. NORRIS, Ph.D.

Professor of Chemistry, Simmons College, Boston.

570 pp., 5½x8. Illustrated. \$2.50 (10/6) net, postpaid.

### **CADY—Inorganic Chemistry**

By HAMILTON PERKINS CADY, A.B., Ph.D.

Professor of Chemistry, University of Kansas.

629 pp., 5½x8. Illustrated. \$2.50 (10/6) net, postpaid.

## MINERALOGY

### **STUDY OF MINERALS**

A Combined Text Book and Pocket Manual

By Austin Flint Rogers, Ph.D., Assoc. Prof. Leland Stanford Univ. 522 pp. 5x7½. Flexible leather. \$3.50 (15s) net, postpaid.

### **PETROGRAPHIC METHODS**

By E. Weinschenk. Trans. by Robt. W. Clark, Instructor in Petrography, Univ. of Michigan. 396 pp. 371 Illus., \$3.50 (15s) net, postpaid.

## MISCELLANEOUS

### **RAILROAD CONSTRUCTION**

By Prof. C. L. Crandall, and F. A. Barnes, Cornell University. 305 pp. Illus. \$3.00 (12/6) net, postpaid.

### **REFRACTORIES AND FURNACES**

By F. T. Havard, Associate Professor, Univ. of Wisconsin. 356 pp. Illus. \$4.00 (17s) net, postpaid.

## THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE COMPARATIVE MEASUREMENTS OF THE CHANGING COST OF LIVING<sup>1</sup>

THE changing cost of living is a fundamental cause of many reactions in the complexes of social phenomena. In fact, it is probable that an economic interpretation of many important historical movements may be developed from future study of such events as possible effects of this probable fundamental cause of radical movements in human societies, such as extensive revolutions and even international wars.

Political economists, at any rate, should hold always before them the idea that mankind is subject first to the primary economic problems of self-maintenance. The changing cost of living is another phrase to denote in a civilized society this factor of relative self-maintenance which is so important in the study of the more primitive societies. Thus, on the side of the consumption of commodities, we may measure the changing cost of the primary necessities in terms of the prices of the markets.

With the development of markets and with the establishing of standard grades for leading commodities, it becomes possible to fix rather definitely comparative prices of all of the more important commodities. As a result, we may compare with a considerable degree of accuracy the fluctuations in the changing cost of living over a series of successive years. Of course, the greater problem of constructing an index number of relative welfare which shall

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

<sup>1</sup> Address of the vice-president and chairman of Section I, American Association for the Advancement of Science, Cleveland, January 3, 1913.

combine in some rational way the general concepts of the cost of living and of the average rates of income may lead eventually to many interesting conclusions, but this problem at the present time is extremely difficult.

In this paper, which is divided into three parts, I shall present, first, the results of original computations of two series of index numbers for American prices. Hitherto, the purpose of index numbers has been chiefly to measure the changing cost of living in order to compare the relative conditions of successive years for the same country.

In the second part of this paper, I have endeavored to present some comparative measurements of the changing cost of living for various countries at the same time, and, incidentally, to devise an international index number, based on some index numbers of the United States, England and France. In the third part, it is interesting to consider briefly various remedies for the instability of the price level, and to inquire whether a society has not within its control indirect methods of reducing absolutely the cost of living—methods which may prove more fruitful than some of the direct methods which have been suggested from time to time in order to secure a relative rather than an absolute reduction.

It is unnecessary to present a technical description of my two series of index numbers for American prices which have been described in the *Quarterly Journal of Economics*,<sup>2</sup> and elsewhere.<sup>3</sup> Suffice it to state that the general method of the Sauerbeck system has been adopted along with certain modifications, some of which were suggested by Forbes and others occurred as practical necessities of the computation.

<sup>2</sup> *Quarterly Journal of Economics*, August, 1910.

<sup>3</sup> Pamphlets on Index Numbers, published by the Gibson Publishing Co., 1910-11.

The two index numbers may be described as the averages of the percentages of the prices of fifty important commodities expressed in terms of the average prices of the years, 1890 to 1899, so that the average price level of the years 1890 to 1899 is the base or one hundred per cent. Two systems of weighting have been used. My first series follows Sauerbeck in the use of the simple arithmetical average. The second series was intended as an approximate continuation of the Dun index numbers which ended in 1907, and which have been published since 1910 as the Gibson index number. The same arbitrary weighting is used in the two series, although the Dun numbers were based on three hundred and fifty commodities and the Gibson on fifty leading commodities. Mitchell<sup>4</sup> has shown that my method of continuing the Dun numbers by using fifty primary commodities rather than three hundred and fifty commodities, many of which are derivative, produces an average difference on the basis of past years approximately of two per cent. The fifty commodities consist of the leading articles of commerce which are most capable of accurate grading.

In the succeeding table,<sup>5</sup> the relative weighting of the various groups, such as foods, clothing, minerals and other commodities, is presented in contrast for various index numbers, in order to suggest the cause of the slight differences which occur in the results reached by the various numbers.

The more heavily the food group is weighted, the more the total index number of all commodities tends to advance. This

<sup>4</sup> *Quarterly Journal of Economics*, November, 1910.

<sup>5</sup> "How Index Numbers are Made," by F. C. Croxton, *Journal of Commerce*, June 2, 1910, and Norton, "Weighting of Index Numbers," June 9, 1910.

TABLE SHOWING WEIGHTING OF GROUPS IN  
VARIOUS INDEX NUMBERS

Groups of Commodities	Sauerbeck's English Index Number, Per Cent.	Norton's American Sauerbeck Number, Per Cent.	Norton's Gibson or Dun Number, Per Cent.	Bradstreet's Index Number, Per Cent.	Bureau of Labor Index Number, Per Cent.
Clothing..	42	44	50	37	26
Food .....	18	18	18	10	29
Other.....	40	38	32	53	45

number,<sup>6</sup> the second column the Dun and Gibson series, and the third column the Dun and Gibson series reduced to the same base as the American Sauerbeck which is the average price level of the years 1890 to 1899 as one hundred per cent. This table is represented graphically by diagram No. 1.

point will be discussed later in this paper. On the other hand, if a large weight is given to manufactured articles, which is the case in the United States Bureau of Labor index numbers, the tendency is to reduce the extent of advance. The group weighting influences the results more than the fluctuations of single commodities, because all commodities of the food group are in a large measure in competition through possible substitution by consumers. The following tables, which are represented by diagrams, disclose the annual averages for the period, 1890 to 1912. The first column contains the American Sauerbeck index

The annual average difference of the two index numbers is two per cent.

To summarize the general movements, a five year average table has been prepared. This table shows how little the weighting has influenced the results in the two series, because the weighting for the food group differs in the two numbers to a less extent than in the case of the other possible comparisons.

TABLE OF ANNUAL AVERAGES OF TWO INDEX NUMBERS FOR AMERICAN PRICES

	American Sauerbeck Index Number	Dun or Gibson Index Number	Percentage Dun Index Number
1890	114	92	109
1891	114	96	113
1892	105	90	107
1893	105	91	108
1894	94	83	98
1895	94	82	97
1896	87	74	88
1897	89	73	87
1898	95	78	92
1899	103	85	101
1900	112	91	108
1901	109	92	109
1902	118	102	121
1903	115	100	118
1904	116	97	115
1905	118	98	116
1906	124	105	124
1907	132	110	130
1908	124	106	126
1909	133	112	133
1910	137	115	136
1911	130	109	129
1912	138	117	138

TABLE SHOWING THE FLUCTUATIONS OF THE FIVE-YEAR AVERAGES OF THE TWO INDEX NUMBERS FOR AMERICAN PRICES

	Dun-Gibson	Norton-Sauerbeck
1890-94	107	106
	— 14	— 12
1895-99	93	94
	+ 21	+ 20
1900-04	114	114
	+ 12	+ 12
1905-09	126	126
	+ 8	+ 9
1910-12	134	135

It is clear that both series of index numbers agree rather closely in showing that we have been living in an era of a prolonged advance in the cost of living during the past fifteen years. In summary, using my American Sauerbeck index numbers, the price level of 1912 is some 59 per cent. above the level of 1896, and compared with 1890, the percentage of advance is 21 per cent.

Such instability in the average price level is unfortunate, and, whether we attribute

the causes solely to forces acting on commodities or to fluctuations in the gold standard or to both causes, the central fact remains that the instability of the price level has caused many hardships to our people.

Let us now construct two index numbers by splitting up the component groups into a food index number and an "other than food" index number, using the average prices of each group, respectively, as the two bases, one hundred per cent. The purpose is to discover the relative movements of the two groups, foods and other than foods, over a period of fifty years. Using the early Dun numbers, reduced to the new percentages, we may present a rough comparison, which, I think, throws light on the situation.

What has happened becomes obvious upon inspecting the following table, which presents the conditions of the price levels of the two groups for selected years, during the period commencing in 1860 and ending in 1912.

TABLE SHOWING THE FLUCTUATIONS OF THE FOOD INDEX IN CONTRAST WITH THE INDEX FOR OTHER COMMODITIES FOR SELECTED YEARS, 1860 TO 1912

	Index Number for Foods	Index Number for Commodities Other than Foods
1860	145	155
1864	293	452
1870	195	200
1875	167	160
1880	138	155
1885	117	112
1888	126	112
1889	124	112

The above statistics are as of January 1.

1890	102	117
1891	121	107
1892	107	107
1893	110	107
1894	102	95
1895	100	95
1896	81	95

1897 .....	83	88
1898 .....	93	93
1899 .....	100	102
1900 .....	105	112
1901 .....	105	114
1902 .....	126	117
1903 .....	117	119
1904 .....	105	112
1905 .....	112	121
1906 .....	119	131

The above statistics are as of July 1.

1907 .....	121	140
1908 .....	129	124
1909 .....	140	126
1910 .....	140	133
1911 .....	136	124

The above statistics are annual averages.

1912 .....	148	131
------------	-----	-----

The figure for July, 1912, is given as the last comparison.

From the average of the low years, 1896-1897 down to 1912, the food group has advanced 80 per cent. and the "other than food" group 43 per cent. Thus, compared with the two low years, 1896-97, foods have advanced nearly twice as much as other commodities. Consequently, the hardships experienced by the classes of the smaller incomes have been very great throughout the world, inasmuch as in all family budgets the percentage spent for foods increases as income diminishes.

But, if we take as representative the figures of 1860 and 1880, leaving out of account the years of the Civil War and of suspension of specie payments, we have 142 for foods and 155 for other commodities. Comparing the conditions of the years 1860 and 1880 with the low years 1896-97, we might have said in 1896 and 1897 that foods had fallen 60 points and other commodities 63 points, or turning the comparison about, food prices as well as other commodities in 1860 and in 1880 were approximately 70 per cent. higher in 1860 and in 1880 than in 1896-97. In

short, food prices are now on the level of 1860 and 1880 and other than food prices are probably 15 per cent. lower.

In summary, since food prices during the past fifteen years have advanced in the United States nearly twice as much as the "other than" food commodities, it is unlikely that the tariff has played so important a part as other causes. Possibly, the tariff is indirectly responsible to some extent in over-stimulating industries of the "other than food" group, and in this way helps to contribute to a deficit proportion of agricultural population.

It seems more probable, however, that the great drop in prices which occurred from 1880 to 1896 represents in part the effects of the unprecedented railroad construction of those days and of the utilization of new inventions in farm machinery, two causes which were at work and must have cheapened the average cost of production of the food group. Naturally, rural population was displaced by farm machinery and we know that thousands of acres of farm lands in the east were rendered of less value by the falling prices, resulting from the application of these two great lines of inventions. As food prices fell and immigration continued on a large scale the wage rates fell, and reduced wages made the cost of production of other commodities lower and naturally the prices went down in sympathy with the lower cost of production.

Food prices are fundamental and "other than food" commodities are derivative through the wage scales which vary with the cost of food. Further, all statistics indicate a steady drift of population away from the food industries to the "other than" food industries, suggesting that the opportunity to secure steady work by labor less securely attached to land has been better in the "other than food industries."

The various movements to extend agricultural credit, to improve systems of distribution and to furnish instruction to the agricultural classes are doubtless in the right direction. But, it is difficult to see how these movements, beneficial as they may prove, can much more than keep pace with similar movements making urban work more productive, such as rapid transportation, trade schools, night schools, etc. In fact, the simple economic force to increase the relative production of foods is, after all, a continued higher level of food prices which will tend to raise farm wages and to stimulate increased production generally in all of the land pursuits.

In order to make comparisons, Sauerbeck's index number for England and the index number<sup>7</sup> for France are reduced to percentages of their own averages for the years, 1890-99, respectively. Thus, the three numbers for each year are simply percentages of the average price level of the decade, 1890-99, for each of the countries. Diagram No. 2 represents the fluctuations of the index numbers of the three countries.

This method affords a system of comparative measurements of the changing cost of living for different countries, but does not necessarily afford a basis for the measurement of the absolute cost of living in dif-

We come now to the second part of this paper, the comparative measurements of the changing cost of living, geographically considered. In the following table, illustrated by diagram, we may contrast the changing cost of living in the United States, England and France.

ferent countries. The latter is, also, an important problem which should be undertaken, the solution of which will require patient critical work in the determination of equal grades of commodities in various countries.

<sup>7</sup> Published monthly by *La Réforme Economique*.

The fourth column contains the records of my international index number which is simply the average of the three preceding numbers for each year. It is interesting to note that American prices, commencing in 1902, advanced much more rapidly than did the price levels of foreign countries, but in the years 1911 and 1912 the margin of difference was considerably reduced.

We are led by our system of comparative measurements of the changing cost of living to the conclusion that world-wide causes are primarily responsible for the prolonged advance in the cost of living. It is probable that accurate statistics would show for India, China, the Argentine, in fact for all countries of the world which are connected by commercial relations, quite similar conditions. My international index number for 1912 shows an advance of 46 per cent. over the low year 1896, in comparison with 59 per cent. for the United

<sup>s</sup> Average based on first ten months.

States, 40 per cent. for England and 43 per cent. for France. It should be noted that the United States numbers have advanced considerably more than the index numbers of foreign countries. But we should remember that commodities "other than" food advanced 49 per cent. in the United States, which is on a parity with the advances of all commodities for England and France.

TABLE AFFORDING COMPARISONS OF 1896 AND 1912, AND 1880 AND 1912

	Advance 1896-1912, Per Cent.	Advance 1880-1912, Per Cent.
United States, foods .....	83	7
United States, other than foods	49	— 15
United States, all groups ....	59	— 6
England, all groups .....	40	— 3
France, all groups .....	43	

The extraordinary advance occurs in the food group of the United States, and it is quite possible that this represents several causes, some of which are technical, some of which are national and some are connected with the chain of sequences produced by an increasing production of gold. It is plain that international causes are at work. During sixteen years following 1880, world prices fell, and during sixteen years following 1896, world prices rose. It is interesting to note that independent computations show that after thirty-two years prices in the United States and in England have recovered very nearly the entire amount of the decline which reached the low point in 1896, and that now world prices are upon an approximate parity with those of 1880.

An excellent opportunity is afforded the recently appointed Industrial Commission to determine the rates of wages prevailing

in 1912 in comparison with 1880, because the cost of living conditions in the two years are very much alike and the years are far enough apart in time to furnish an excellent basis for sound conclusions regarding the relative rates of income of all classes of labor. The results would probably surprise those economists who distrust the possibilities of social progress.

finally recommended this plan to congress. Endorsements have been given by resolutions of the New York Chamber of Commerce and more recently by the International Congress of Chambers of Commerce of the world. The Sulzer bill, providing for such a commission, is now before congress.

The work of such an international com-

In 1907, the writer proposed the appointment of an international commission<sup>9</sup> to study the causes of the advancing price level, believing international causes were chiefly responsible. In 1912, as a result of the Washington meetings, when Senator Burton, vice-president of the American Association for the Advancement of Science, read a paper on the causes of the high prices and Professor Irving Fisher spoke before the American Economic Association in favor of the proposition, President Taft

<sup>9</sup> *Yale Review*, 1906, and *Moody's Magazine*, 1907.

mission on the cost of living might well include the computation of a series of identical numbers for the principal countries of the world. Such index numbers should disclose the absolute as well as the relative changing cost of living as measured by fifty to one hundred leading commodities, by providing for identical commodities, identical grades and identical weighting. Such an investigation is quite as proper for the Carnegie Institution or for the United States Bureau of Standards to undertake, inasmuch as such measurements of price levels are not only very central,

but also pressing problems of economic research.

If a complete and thorough investigation should be undertaken to show the relations of the price movements of the principal countries, it is probable that the composite result expressed in the form of an international index number would not differ greatly from my international index number in statistical significance. The international index number is represented by diagram No. 3.

What would this result mean? I think that we should have in a well-defined form an approximation to those two concepts concerning which Jevons wrote, namely, first, an international multiple standard of value, and, second, a method of achieving the use of international money by making the present currency of all nations token money under the new standard of value.

Since we hold that the evidence shows

that international causes are largely responsible for the advance in prices, we may omit consideration of many of the remedies which have been proposed from time to time which, if applied, would be essentially local in their operation.

What are the international causes which could have produced this common rise of more than forty per cent. since 1896 in three countries, and what could have been the common international causes for the fall in prices of the period, 1860-1896? The writer believes that the international causes are three in number. First, cheaper transportation was responsible for a part of the decline, 1880-1896, and the cessation of railroad building on a large scale coupled with increasing consumption resulted in the recovery following 1896 in some part. Second, extensive use of farm machinery lowered the cost of production throughout the world and the use of labor-saving machinery on farms resulted in a relative displacement of farm labor, causing the relative exodus from the agricultural occupations. This caused a part of the decline in food prices down to 1896. This table of averages of food prices in comparison with the prices of other commodities indicates what have been the changes in the two groups by five-year periods. Diagram No. 4 discloses the trend of these averages.

TABLE SHOWING FIVE-YEAR AVERAGES OF FOOD INDEX AND "OTHER THAN" FOOD INDEX

1880 and 1885 ...	128	124
	— 3	— 12
1888 and 1889 ...	125	112
	— 17	— 5

	— 17	— 12
1895-99 .....	91	95
	22	21
1900-04 .....	113	116
	11	— 8
1905-09 .....	124	108
	17	21
1910-12 .....	141	129

Naturally, lower prices for foods resulting from cheaper transportation and the displacement of farm labor by agricultural machinery resulted in a world-wide relative urban movement. Undoubtedly, several years of continued high food prices will prove the most efficient cause to encourage an increased production of foods. All legislation making agricultural credit available and affording opportunities to acquire land on favorable mortgage conditions will contribute to this end.

The third international cause is undoubtedly the increased production of gold<sup>10</sup> commencing in the late nineties. Just as excess of paper money in the Civil War period inflated prices, so the excessive gold supplies have inflated international prices, and all credit devices economizing the use of gold have helped to magnify the tendency towards inflation. Possibly, the greater advance in food prices of the United States is due to the greater influences of the first two international causes in the United States, and the so-called gold influence may be responsible for the larger part of the common advance. However, the relative importance of the three international causes may not be accurately estimated.

But the facts remain that the instability of the international price level is a disturbing element and the difficulty is that we measure all commodities in terms of one commodity rather than in the terms of fifty or more important commodities. In 1910, the writer recommended the establishment of an optional multiple standard,<sup>11</sup> possibly by the Bureau of Standards. In referring to this proposal, the Massachusetts Commission on the Cost of Living says:

<sup>10</sup> Norton's "Gold Flood," *Cosmopolitan Magazine*, June, 1910.

<sup>11</sup> Norton's "The Remedy for the High Prices," *Independent*, February 10, 1910.

It is hard to see how any harm could come from giving official aid to the maintenance of such a standard for the use of any borrowers and lenders who chose to adopt it. In the event of a long continuance of the upward movement of prices, its use might prevent serious injustice and great hardship. We recommend that our senators and representatives consider the expediency of advocating its establishment.

The two classes which suffer most by the instability of the price level are wage earners and investors.<sup>12</sup> If wages were payable in the multiple standard, wages would fluctuate with cost of living and strikes would be diminished to a very great extent. If long time obligations were expressed in the multiple standard, creditors and debtors would exchange equal amounts of purchasing power. Now, all of these classes—the manufacturers, the labor unions, the bankers and the investors are intelligent. Why not leave the determination of the standard to agreement, and as a first step simply create an optional multiple standard which could be used when specified in wage contracts and in long time obligations.

The reasonable basis of an optional multiple standard would win its way and the economic benefits experienced would counsel its extension. By proper organization of clearing houses under a national clearing house,<sup>13</sup> by regulation of storage-warehouse warrants and the clearances of all classes of stock and produce exchanges, all transactions could be made either by the present currency made token money under a multiple standard, or by clearances direct in the optional multiple standard, since the holder of one unit of the optional multiple standard could convert into the value of any other commodity, if all prices

<sup>12</sup> Norton's "Stocks as an Investment when Prices are Rising," *Securities Review*, September, 1912.

<sup>13</sup> Norton's "Central Bank as a Federal Clearing House," *Moody's Magazine*, September, 1910.

were expressed in terms of the optional multiple standard, which involves simply a change of or a new definition of the dollar. This would be the final result, long anticipated by the economists. I quote from Patron's monograph on the Bank of France, prepared for the Monetary Commission:

The interesting evolution of exchange which we are witnessing and which is familiar to everybody seems to be leading us, after the well-defined periods of barter and money, to a system of mere clearing of balances. All exchange operations would then be settled by simple book transfers. Coin reduced to money of account, would cease to play any real part. Economists are ever thinking of a return to barter, which would complete the cycle, bringing us back to the original state after thousands of years and combinations of all kinds. Such would be the course of this evolution.

But, as changes in monetary standards come very slowly, because men are unwilling to change the old landmarks without most careful investigations, we do not anticipate that the vision originally seen by Jevons will come to pass at once, even though the economists are again discussing this question after the lapse of many years.

If prices continue to mount actively, the agitation for such a change will occur with increasing force. But, we must remember, so far as the gold factor is concerned, that there are eastern nations with vast populations, capable of absorbing large quantities of gold under the stimulus of the western learning which is working as a yeast of progress among them. Further, we can steady prices and produce a declining tendency by requiring a larger proportion of gold in the reserves of the banks. This would at the same time strengthen the whole credit system. If we should go farther and require minimum flexible<sup>14</sup> reserves, higher in dull seasons and lower in

active seasons, and incidentally higher on the average, as just suggested, a considerable fluctuating tendency would be eliminated.

After all, the Fabian policy lies before us, and looking ahead, it is probable that the agitation over this subject will be largely influenced by the course of commodity prices during the coming two years. This diagram discloses the quarterly fluctuations of my new international index number for the past five years. It is probable that we have passed the high point for two years or more, and that lower prices are now in order.

TABLE OF MONTHLY INDEX NUMBERS—NORTON  
INTERNATIONAL SERIES

	1907	1908	1909	1910	1911	1912
Jan. to March.....	125	117	116	125	124	129
April to June.....	127	116	118	125	124	135
July to Sept.....	126	115	119	125	125	132
Oct. to Dec.....	122	115	121	123	126	

If this position shall turn out to be correct, we shall be in a better position two years from the present time to estimate whether the growth of population, the absorption of gold by eastern nations and the higher level of prices shall have overtaken the rate of increase of gold production sufficiently to produce an era of falling prices. When this occurs, as it will occur, sooner or later, we shall have the reverse agitation of the agricultural classes against falling prices such as our country witnessed in the Populistic agitations of the early nineties.

The money question, which has been a political issue, constantly changing in form and exceedingly disturbing to business, will continue to be with us so long as the instability of the price levels continues.

One result of the prolonged advance in the cost of living has been to emphasize the necessity of "economy," not only personal,

<sup>14</sup> Norton's "Statistical Studies in New York Money Market," 1901.

but also "political," quite in the original sense of political economy. The very name of the movement which in a way is a constructive reaction from the economic stimulus of a lessened purchasing power is significant. I refer, of course, to the conservation movement. The word conservation, although vague, stands for the diminishing of wastes. In the conservation movement, we have a return to the original purposes of "political economy." The items which make up the cost of living as represented by an average family budget suggest plainly the directions in which the prevention of wastes may prove most fruitful. In the attempt to reduce the absolute cost of living, society wages an eternal warfare against the destructive wastes of nations,<sup>15</sup> which are preventable war, preventable ignorance, preventable sickness, whether physical, intellectual or moral, preventable death, preventable accidents to life and property, and preventable lack of opportunity which may delay or prevent the productivity of exceptional minds like those of Edison and Burbank, which exist in all degrees in certain proportions in the population. The latter waste is the greatest waste which society still permits. The public school system is an institution created to furnish equal opportunity for education, but it is probable that a system of vocational guidance for exceptional children, *i. e.*, above the average, would prove an extremely profitable policy for a nation to undertake on a large scale.

If we admit that in a population some are exceptional beyond others in intelligence, in foresight and in inventive capacity—and we know this to be true by the prevalence of idiots, insane persons, criminals and paupers, classes below the aver-

age—it follows that the larger the population of the same strain, the greater will be the number of exceptional minds above the average. It is self-evident that the national dividend of a better civilization is created by the exceptional minds of a nation for the higher utility of all. We reduce absolutely, not relatively, the cost of living when we discover a cheaper method of controlling the matter and the forces of the world. Thus, a natural tendency to progress<sup>16</sup> is inherent in an increasing population, unless checked by the destructive wastes of nations. Nor can we overestimate the importance of ethical and hygienic standards in the study of political economy. Our measurements and standards of utility must be based on ethical and hygienic values rather than on conceptions of opulence or desirability.

By ethical standards, we mean to include among others the more enlightened conceptions of jurisprudence, and by hygienic standards the well-balanced judgments of enlightened medical and sanitary experts. But the guidance of present statistics of the cost of living supplemented by vital statistics is essential to a balanced judgment and the lack of accurate statistics on social and economic subjects is well known. Without measurements, our conclusions must be vague.

J. PEASE NORTON

NEW HAVEN, CONN.

#### PLANS FOR A GREATER UNIVERSITY OF MONTANA

BETWEEN forty and fifty prominent citizens of all parts of the state of Montana met at Helena, December 23, and organized the Association for the Creation of a Greater University of Montana. This is to be brought about by the consolidation of the present iso-

<sup>15</sup> Norton's "Economic Advisability of a National Department of Health," *Journal of American Medical Association*, August, 1906.

<sup>16</sup> Norton's "Cause of Social Progress and the Rate of Interest," *Popular Science Monthly*, September, 1910.

lated institutions of higher learning, the university, the agricultural college, the normal school and the school of mines at some city which is desirably situated. The plan is supported by the proposed conversion of the plans and equipment that would otherwise be abandoned into a system of polytechnic high schools.

A comprehensive outline of the change sought to be effected is given in the constitution and by-laws of the association, organized at that time before the meeting of the board. This follows:

The name of the organization shall be "The Association for the Creation of a Greater University of Montana."

The purpose of this association shall be:

1. To consolidate the four higher educational institutions of the state in order to prevent the educational and financial waste brought about by the maintenance of separate and isolated institutions.

2. To establish, instead of the four institutions, a greater University of Montana to be situated in or near some city suitable by reason of its railroad connections, climate and water and health conditions to be a great seat of learning.

3. To work for the creation of a splendid system of polytechnic high schools which are at the present time so much needed; this to be brought about by means of (a) the utilization of all the present plants that would otherwise be abandoned, (b) the utilization of the military post at Fort Assiniboine if the government turns it over to the state; (c) the establishment of similar schools in other sections of the state as they may from time to time be needed.

4. To impress on the attention of philanthropic persons, especially men of great means, the desirability of aiding the development of the University of Montana, through the provision of buildings and endowments.

5. To arouse public sentiment in favor of education and to arouse the enthusiasm of the people to the unsurpassed educational possibilities of the great commonwealth of Montana.

The state board of education, after giving a hearing to the representatives of this resolution, unanimously adopted resolutions recommending that the legislature consolidate the institutions and pledging the members to do

all within their power to encompass the result sought.

#### THOMAS HARRISON MONTGOMERY

At the recent meeting of the American Society of Zoologists in Cleveland, Ohio, the following resolution was submitted by Dr. A. G. Mayer on behalf of the executive committee. The resolution was then approved by a rising vote of the society.

Never has a deeper sense of irreconcilable sorrow fallen upon us of this society than that following the announcement of the death of Thomas Harrison Montgomery on the nineteenth day of March, 1912, at the early age of thirty-nine years.

Other friends, leaders in science, have gone before, but they were full of years and the labor of their lives was as a story well nigh told; but with Montgomery the tasks that lay before him were those of the greater years of life, that period of intellectual fruition for the harvest of which his years of toil and training had been a preparation.

While thus but upon the threshold of his middle years, science lost him; but irreparable as these things be, it is as our friend we mourn him most.

No ordinary motives actuated him in his scientific work, for personal ambition never clouded his simple love for truth wherever truth might lead him.

It is to unselfish men such as he that great opportunities are entrusted, and the equipment and organization of the new Zoological Laboratory of the University of Pennsylvania was a task he had all but completed, and this will serve as a fitting monument to his ability as an executive.

On the scientific side, he was the author of nearly one hundred publications, and it would be impossible to write a text-book upon the rôle of the chromosomes in the determination of sex without referring to his crucial labors in this field.

It is seldom that we see a man even far advanced in years attain to the achievement he accomplished. Yet as our friend and our companion we mourn him most, for science will and must be advanced; but to us there ever will be but one Montgomery, the generous friend, sympathetic and simple, Montgomery the gentleman who loved us and whom we loved.

W. C. CURTIS,  
*Secretary*

## SCIENTIFIC NOTES AND NEWS

THE Elisha Kent Kane gold medal of the Geographical Society of Philadelphia was presented to Professor William Morris Davis, of Harvard University, on January 28. On that evening Professor Davis made an address on "Human Response to Geographic Environment," inaugurating the Heilprin memorial lectures. Professor Davis will receive the Culver medal of the Geographic Society of Chicago, at the annual dinner on February 19.

PROFESSOR GEORGE HERBERT PALMER, Alvord professor of natural religion, moral philosophy and civil polity, and Professor Francis Peabody, Plummer professor of Christian morals, have given their final lectures at Harvard University. Professor Palmer has served the university for forty-three years and Professor Peabody for thirty-eight years.

PROFESSOR GEORGE F. SWAIN, of Harvard University, has been elected president of the American Society of Civil Engineers.

DR. CHARLES L. DANA has been elected president of the New York Psychiatric Society, and Dr. S. Ely Jelliffe, president of the New York Neurological Society.

MAJOR E. H. HILLS, F.R.S., has been appointed honorary director of the Durham University Observatory.

SIR SYDNEY OLIVIER, governor of Jamaica, has been appointed to be permanent secretary of the British Board of Agriculture and Fisheries.

DAVID R. KELLOGG, Ph.D. (Ohio State, '12), has accepted a position as research chemist in the Bureau of Mines, with headquarters at San Francisco.

DR. R. C. BENEDICT has been appointed editor of the *American Fern Journal* to succeed Dr. Philip Dowell, who declined to be considered for reappointment.

DR. A. HRDLÍČKA, of the United States National Museum, has sailed for Peru and Bolivia, with the object of extending his former work in those countries, and securing further anthropological collections. He expects to return in April.

DR. ROLLIN T. CHAMBERLIN, of the University of Chicago, lectured on a visit to Brazil, before the Geographical Society of Chicago, on January 24.

DR. J. ARTHUR HARRIS, of the Carnegie Institution, spoke before the Society of Sigma Xi of Washington University on January 23, his subject being "The Francis Galton Laboratory for National Eugenics and its Work."

BEFORE the Society of the Sigma Xi of Columbia University, Professor Henry C. Sherman lectured on January 16, on "Progress and Problems in Food Chemistry."

DR. VICTOR C. VAUGHAN, dean of the School of Medicine of the University of Michigan, addressed the Science Club of the University of Wisconsin, January 16, on "Eugenics, or Race Betterment."

THE Semon lectures on laryngology were delivered at University College on January 22 and 24, by Dr. Peter McBride, the subject being "Sir Felix Semon: His Work and its Influence on Laryngology."

MR. FRANCIS BLAKE, who did important work under the U. S. Coast Survey from 1866 to 1878, and subsequently obtained distinction by the invention of the telephone transmitter and other electrical apparatus, died at his home in Weston, Mass., on January 19, aged sixty-three years.

PROFESSOR JONATHAN HYATT, known for his contributions on insect anatomy, former president of the American Microscopical Society, died at his home in New Rochelle, on December 20, aged eighty-six years.

MRS. WILLIAM BASHFORD HUFF, formerly demonstrator in physics in Bryn Mawr College, the author of contributions to physics and mathematics, died on January 19, aged twenty-nine years. In 1898 she married Dr. William Bashford Huff, professor of physics at Bryn Mawr College.

DR. WILLIAM HOWSHIP DICKINSON, a distinguished English physician and pathologist, died on January 9, aged eighty years.

MR. B. LEIGH SMITH, known for his work in Arctic exploration, died on January 4, at the age of eighty-five years.

THE U. S. Civil Service Commission announces an open competitive examination on February 26, for forest pathologist, to fill a vacancy, at a salary ranging from \$1,980 to \$2,400 a year, in the Bureau of Plant Industry, Department of Agriculture, for service either in Washington, D. C., or in the field. On February 26 there will be examinations for scientific assistant of soil surveying in the Bureau of Soils, at salaries ranging from \$960 to \$1,200 a year, and for assistant irrigation engineer in the office of Experiment Stations at salaries ranging from \$1,200 to \$1,600.

ARTICLES of incorporation for the "Rockefeller Foundation" to administer a fund of \$100,000,000 to be given by Mr. John D. Rockefeller, were passed on January 21 by the House of Representatives by a vote of 152 to 65. The measure now goes to the Senate. The bill, introduced by Representative Peters, of Massachusetts, names as the incorporators to administer the fund, John D. Rockefeller, John D. Rockefeller, Jr., Frederick T. Gates, Starr J. Murphy, Harry Pratt Judson, Simon Flexner, Edwin A. Alderman, Wickliffe Rose and Charles O. Heydt, and such persons "as they may associate with themselves." The object of the foundation is "to promote the well-being and to advance the civilization of the peoples of the United States and its territories and of foreign lands in the dissemination of knowledge, in the prevention and relief of suffering and in the promotion of eleemosynary and philanthropic means of any and all of the elements of human progress."

At the instance of the Southern Commercial Congress the governors of some of the states are appointing two delegates each to go to Europe about April 26 and to remain there three months studying the system of rural credits and land banks there existing, with a view to adapting the system to this country.

ARRANGEMENTS have been completed by which the American agency for the following journals of the Cambridge University Press will be in the hands of the University of Chicago Press, beginning January 1, 1913: *Biometrika*, *Parasitology*, *Journal of Genetics*, the *Journal of Hygiene*, the *Modern Lan-*

*guage Review*, the *British Journal of Psychology* and the *Journal of Agricultural Science*.

The will of Alfred Samson, who died recently at Brussels, provides for an endowment of \$500,000 for the Prussian Academy of Sciences and \$100,000 for the Bavarian Academy of Sciences, at Berlin and Munich. The endowments are stated to be for investigations which afford a prospect of raising the morality and well being of the individual and of social life, including the history and prehistory of ethics, and anthropologic, ethnologic, geographic, geologic and meteorologic influences as they have affected the mode of life, character and morals of man.

THE Woman's Medical Association of New York City offers the Mary Putnam Jacobi Fellowship of \$800 available for postgraduate study. It is open to any woman graduate of medicine. The amount of the endowment to date will permit of a biennial award, and upon the completion of the fund, this will be made annually. The fellowship will not be awarded by competitive examination, but upon proof of ability and promise of success in the chosen line of work. Applications for the year 1913-1914 must be in the hands of the committee on award by April 1, 1913.

ON February 6, 7 and 8, 1913, in the electrical laboratory of the University of Illinois, the students of the department of electrical engineering will give their triennial electrical show. Although under student management, it will be by no means wholly a student show, as many manufacturing and sales companies in the electrical trade will offer exhibits. Among the exhibits will be isolated lighting plants, heating and cooking accessories, telephone, telegraph, and wireless apparatus, lifting magnets, motor controllers, high frequency machinery and a complete electrically operated café. Student demonstrators or manufacturers' representatives will be in charge of each exhibit. One special feature planned in connection with the show is an exhibit of all types and methods of electrical lighting. This will be in charge of students of electrical illumination who will discuss with interested

visitors the best and cheapest ways of lighting their buildings. Under the general direction of Dr. E. J. Berg, head of the department of electrical engineering, a business organization composed of graduate and undergraduate students is carrying on the entire work incident to the show.

THE Wagner Free Institute of Science of Philadelphia announces a course of four free public lectures under its Westbrook Free Lectureship Foundation on Conservation of Natural Resources, as follows:

January 18—Gifford Pinchot, president, National Conservation Association, "A Glance over the Field."

January 25—Marshall O. Leighton, chief hydrographer, U. S. Geological Survey, "Water as a Resource."

February 1—Overton W. Price, vice-president, National Conservation Association, "What shall we do with our Forests?"

February 8—Joseph A. Holmes, director, Bureau of Mines, Department of the Interior, "Saving Life and Resources in the Mining Industry."

THE Ecole D'Anthropologie de Paris announces the following courses for the year 1912-13:

Anatomic anthropology: Anatomic characters of fossil man. Professor R. Anthony.

Prehistoric anthropology: Art and industry of the Magdalenians and the neolithic populations. Professor L. Capitan.

Zoologic anthropology: Appearance of man in Europe. Hypotheses as to anthropologic centers. Professor P. G. Mahoudeau.

Ethnology: Study of Mendelian heredity—facts, laws, anthropologic applications. Professor G. Hervé.

Physiologic anthropology: Intelligence in the human species, according to race, sex, age, social categories and the individual. Professor L. Manouvrier.

Comparative ethnography: Origin and evolution of clothing and ornament. Professor A. de Mortillet.

Sociology: The social maladies. Professor G. Papillault.

Anthropologic geography: Geographic relations in prehistoric and historic times. Professor F. Schrader.

Ethnography: The French colonies, Morocco, Central Africa. Professor S. Zaborowski.

Linguistics: History of linguistics, the higher languages. Assistant Professor J. Vinson.

Series of special lectures by MM. Dubreuil-Chambardel, Franchet, Kollmann and Paul-Boncour.

THE Eugenics Education Society, as we learn from *Nature*, has arranged for three courses of lectures upon the groundwork of eugenics, to be given at the Imperial College of Science, South Kensington, from January to December, 1913. In the spring term (January to March) there will be a course of twelve lectures on elementary biology, with special reference to the reproductive system, by Mr. Clifford Dobell; in the summer term (April to July), a course of twelve lectures on heredity, including evolution, genetics, and heredity in man, by Professor R. C. Punnett, F.R.S.; and in the autumn term (October to December), a course of twelve lectures on statistical methods applied to some problems in eugenics, by Mr. G. Udny Yule. In connection with the Francis Galton Laboratory for National Eugenics, a course of six lectures will be delivered at University College, London, by Professor Karl Pearson, F.R.S. (Galton professor of eugenics), Miss Ethel M. Elderton, Dr. David Heron and Mr. W. Palin Elderton. These lectures will be given on Tuesday evenings at 8 P.M., beginning February 11, 1913, and will deal with the following subjects: heredity, environment and parental habits in their relation to infant welfare; heredity of piebaldism and of albinism in man; the relation of fertility in man to social value in the parent; some points with regard to our present knowledge of heredity in cases of feeble-mindedness; the mortality of the phthisical under sanatorium and tuberculin treatments; and recent studies of heredity in dogs, and their bearing on heredity in man.

THE Berlin correspondent of the *Journal* of the American Medical Association writes that the regular general meeting of the "Leipziger Verband zur Wahrung der wirtschaftlichen Interessen der deutschen Aerzte," was held at

Leipzig on November 25. It now includes over 75 per cent. of the German medical profession, the membership being about 25,000 on October 1, 1912. The work of the association requires the services of 1,280 confidential agents and superintendents who serve without pay. During the past business year the department for exchanges of practise placed 3,600 physicians in suitable positions. The widows' fund, a fund made up of voluntary contributions, distributed to the widows of physicians \$9,500. In preparation for the struggle which is expected to occur against the *Krankenassen* in consequence of the new insurance law, a fund has been provided by contributions of at least 100 Marks, loaned without interest, which now amounts to more than \$250,000. The loan and death bureau, founded by the association in 1910, now includes 14,000 members. This serves the double purpose of making loans to its members on sufficient security and of providing a death benefit, which varies according to the contributions from \$50 to \$500. The bureau has hitherto loaned about \$165,000.

#### UNIVERSITY AND EDUCATIONAL NEWS

By the will of the late Mrs. Lucy Wharton Drexel \$70,000 is bequeathed to the museum of the University of Pennsylvania, and \$20,000 to the University Hospital.

THROUGH Dr. Andrew D. White, Mr. Andrew Carnegie has given to Cornell University \$25,000, which will probably be used as a student loan fund.

To parallel the work of the *Deutsches Haus* of Columbia University an anonymous donor has presented to the trustees the house at 411 West 117th Street as *La Maison Française*. The building, of which the cost is estimated at \$30,000, will be used as a center for the study of French literature and civilization. Columbia University has also received a gift of \$8,000 from Mr. Edward D. Adams, of New York, for the equipment of a precision laboratory for physical research, to be known as the Ernest Kempton Adams ('97S) Precision Laboratory.

By the will of Levi N. Stewart, of Minneapolis, Dartmouth College receives \$75,000 and Bowdoin College and Bates College \$50,000 each. All the bequests are unconditional. Mr. Stewart was a former inhabitant of Maine and a graduate of Dartmouth College.

TUFTS COLLEGE is given the residue of the estate of Miss Hannah S. Moulton, of Kensington, N. H., estimated at about \$25,000, for the founding of a scholarship.

THE recommendations of President Schurman, of Cornell University, in his latest annual report as to faculty participation in the university government were considered by the board of trustees at their recent meeting. The board recognized the desirability of closer relations and greater cooperation between the faculty and the board of trustees in matters pertaining to the administration of the university's affairs and referred the matter to a committee of five, to be appointed to consider and report recommendations to the board at a later meeting, final action to be deferred until after President Schurman's return.

THE regents of the University of Minnesota have voted to refer to the university senate for consideration the plan of granting six months absence on full pay in lieu of sabbatical leave for a year on half pay. It was also voted to refer to the same body the question of members of the staff accepting outside employment without the approval of the dean and the president.

PROFESSOR LUDWIG SINZHEIMER, of the University of Munich, will join the faculty of the University of Wisconsin for the second semester, taking the place of Professor Richard T. Ely, who has been appointed lecturer at the University of London during the remainder of the year.

MR. M. J. PRUCHA has been promoted from an instructorship to an assistant professorship of plant physiology in the Cornell College of Agriculture.

JOHN W. GILMORE, president of the College of Hawaii, has been appointed head of the department of agronomy of the college of agriculture of the University of California and

will take up his work at Berkeley next September.

DR. RICHARD P. STRONG, director of the Government Biological Laboratory at Manila, and professor of tropical medicine in the Philippine Medical School, has been appointed head of a newly established department of tropical medicine in the Harvard Medical School.

#### DISCUSSION AND CORRESPONDENCE

##### ON COMPARING AMMONIFYING COEFFICIENTS OF DIFFERENT SOILS

In the issue of *SCIENCE* for November 29, 1912, there appears on page 761 a special article under the above caption by Professor Chas. B. Lipman, of the University of California. The brief is devoted almost entirely to a friendly criticism of certain conclusions drawn by the writer regarding a comparison of the ammonifying efficiency of certain Colorado soils with that of soils from other stated localities. Such criticisms, when presented in the proper spirit, and there is no reason to feel that this has not been the case here, are always welcome and are often helpful.

Now, the writer admits quite freely that the fundamental facts brought out by Professor Lipman are very largely true. However, he is not willing to concede so readily that the criticisms based upon these facts as applied to the case at hand are altogether warranted.

Among Professor Lipman's comments is to be found the following:

Despite the fact that Professor Sackett makes some qualifying statements in discussing the comparisons, he does not seem to attach importance enough to some factors of which he appears to be fully cognizant and gives no consideration to other very important factors.

In support of this statement, the critic offers the following, all of which tends to leave the impression that the writer has not taken these matters into consideration and given them due weight, in spite of the fact that statements to the contrary appear in the original publication<sup>1</sup> referred to:

<sup>1</sup>Bulletin 184, Colorado Experiment Station, June, 1912, Part I., "The Ammonifying Efficiency of Certain Colorado Soils."

The writer (Lipman) of this note fails to appreciate the value of a comparison of the ammonifying powers of various soils as obtained by different investigators whose methods vary as much as ours do to-day.

The writer in selecting the results of the work of others for comparison was particular to choose only such as were obtained in laboratories where practically the same methods have been employed, and wherever there has been any departure from the procedure of the majority, such departure has been indicated.

On page 21 of the bulletin cited occurs this statement:

The methods employed by the different experimenters have been practically the same, so the results should be comparable.

Again, Professor Lipman points out the importance of all investigators employing the same brand, in fact the same lot, of dried blood in comparative work, intimating that the writer has ignored this point. This would be an ideal condition, most certainly, the desirability of which no one questions, but how impractical! If investigators would submit the analysis of such materials as the above along with their reports, this would assist greatly in comparative studies. The writer is fully aware that dried blood may vary all the way from 6 to 13 per cent. total nitrogen, and had he not had clearly in mind the possible influence of its composition on ammonification, why should he have called the reader's attention to this statement on page 23 of Bulletin 184?

With the exception of the New Jersey figures, the percentages given in Table No. 6 are based upon blood meal containing 13.05 per cent. of total nitrogen, and cottonseed meal with 7.84 per cent. total nitrogen. In the New Jersey work, Lipman (J. G.) states that the blood meal and cottonseed meal contained, respectively, 13.18 per cent. and 6.405 per cent. total nitrogen.

Unfortunately, the composition of the blood meal employed by the different investigators cited in the comparative studies, with one exception, was not given, and consequently the writer, in order to get some basis for comparison, was compelled to compute the results

given on the basis of blood meal containing 13.05 per cent. total nitrogen, such as was employed by the Colorado Station. To the end of making available more complete data for comparative studies, the writer would take this occasion to urge those who are engaged in research work to be less reluctant about giving the details of their investigations, for it is obvious that comparative work is impossible and worthless except it be carried out with a strict observance of points of technique.

Professor Lipman refers to the importance of having a large number of soils in any comparative study:

It must also be added here that the comparison of only a few soils can not be invested with much importance, even if the soils are described by similar names.

In this matter, his point is well taken, but when the data do not exist, we must be satisfied with the information at our disposal. Moreover, it seems to the writer that a comparison of the ammonifying efficiency of twenty-seven niter soils with that of ten soils selected at random in Colorado and elsewhere should have more weight than the critic would concede.

Again, Professor Lipman writes:

It is, of course, obvious that sandy loams may embrace soils of very widely differing natures and that no just comparison can be made between a sandy loam, so called in one district, with a sandy loam so called in another district.

If this comment is intended as a criticism of Bulletin 184, it is absolutely without foundation, for no place in this publication can there be found any statement which suggests, implies or asserts a comparison of soils on a physical basis.

The one very important factor which the writer is said to have given no consideration, and upon which Professor Lipman has dwelt at some length, is what appears to be a radical departure from the normal in the method of preparing the soil cultures for studying ammonification. Professor Lipman states that "Professor Sackett sterilizes his soils with mercuric chloride and then rinses them with sterile distilled water prior to inoculation with

a soil infusion." Then follows a critical discussion of this method.

The writer begs to state in defense of this assertion that *no such procedure has ever been practised* in his laboratory and probably never will. This seemingly direct contradiction resolves itself into a rather amusing circumstance when it is learned that Professor Lipman has gained this erroneous impression, upon which he has grounded his chief criticism, from his failure to observe certain punctuation marks in the crucial sentence. On page 4 of Bulletin 184, this sentence occurs:

As soon as the soils were air dry, which seldom requires more than twenty-four hours in our atmosphere, each was ground in a glass mortar, sterilized with mercuric chloride and subsequently rinsed with boiled, distilled water, and passed through a thirty-mesh wire sieve.

From this, it is perfectly clear to the writer that it is the glass mortar which was sterilized with mercuric chloride and subsequently rinsed with boiled, distilled water. However, Professor Lipman makes it the soil which received this treatment, and thereby hangs the tale.

As confirming the Colorado investigations, the writer is pleased to learn that on several occasions Professor Lipman has noted a high ammonifying efficiency in soils of California, which contain abnormal amounts of nitrate, as well as in certain soils obtained from the vicinity of Grand Junction, Colorado.

#### THE TERMS SEGMENT AND SEGMENTATION IN GEOLOGY

THE terms segment and segmentation which are so conveniently and widely used in the biologic sciences have not found their way into geologic literature to a very notable extent, although they seem to be well suited to geologic science. In searching for a general term which could be applied to a minor part of the earth and having the dimensions of a solid, the word segment appeared to me as the most convenient, and on reflection I recalled

that it has already been made use of in Chamberlin and Salisbury's text-book of geology, in discussing continental and oceanic segments. If it is applicable to major elements why not to minor ones as well? The parts cut off by a fault or included between faults might be called fault segments and the terms upthrow segment, downthrow segment, overthrust segment and underthrust segment would be convenient and would obviate such expressions as "the area adjacent to the fault on the upthrow side" and others which are equally unsatisfactory. Other usages of the term would follow naturally. The Colorado plateau may be cited, as an example of segmentation by faulting.

After writing the above I read the "Report on the Investigation of the Geologic Structure of the Alps," by Willis<sup>1</sup> and found the following usages of the term segment:

Each of these minor scarps is the western face of a segment of the range. . . .

It is an example of major and minor thrusting with two somewhat divergent directions of displacement and with diversities of folding in the several segments.

These are the only quotations which I can cite, but there are no doubt others which may occur to the reader. The fact that geologic text-books and glossaries do not include or define the term segment is no reason against its being used, since they follow usage rather than establish it.

GEO. I. ADAMS

IS THE "ACADEMIC COSTUME" WORTH WHILE?

TO THE EDITOR OF SCIENCE: Early in October last I accompanied my wife to the celebration of the seventy-fifth anniversary of Mt. Holyoke College, where she graduated in 1873. I was deeply and favorably impressed with the comprehensiveness and significance of the program and with the executive ability manifested by those—chiefly women—charged with its fulfillment.

Of the several functions, however, I wit-

nessed but one, and that only in part. The "Intercollegiate Commemoration Exercises" began with a procession of some score presidents and delegated professors arrayed in full "academic costume." The sentiments aroused by it banished all desire to remain. (The following discourses, however, were admirably reported and were read afterward with interest and enlightenment.)

At Cornell University, some years ago, as a member of a committee on the subject, I co-operated in preventing the adoption of an arbitrary requirement; when, nevertheless, parti-colored ceremonial garments were worn by most of my colleagues, I excused myself from commencement exercises; hence I was quite unprepared for the gorgeous spectacle at Mt. Holyoke.

I tried to comprehend how mature, modest, civilized and learned persons could don garments indicating, on the one hand, an assumption of superiority and, on the other, a childish delight in bright colors and startling combinations (one was so "loud" that it seemed doubtful if the wearer could make himself heard). Nor could I refrain from speculating as to how far the addition of feathers and paint might complete the barbaric *ensemble*, arouse more keenly the curiosity of the uninitiated, and more effectually dazzle the eyes of groundlings.

Since then there have been sent me colored plates of the various academic costumes according to British and American usages, some courteous letters and offers of fuller information, and a pamphlet entitled "The International Bureau of Academic Costume, Albany, N. Y., July 27, 1902." To those interested I commend the paragraphs in that publication at the middle of page 5 and near the top of page 11. Candid and careful consideration of the claims there made confirms the opinion formed when the subject was first broached, viz., excepting, perhaps, the plain gown for the first degree, obviating social distinctions, the so-called "academic costume" is ostentatious, needless, childish or barbaric, and inappropriately expensive; its rapid and general

<sup>1</sup> Smithsonian Miscellaneous Collections, Vol. 56, No. 31, 1912.

adoption, so far from evidencing its intrinsic value and probable permanence, exemplifies the survival of simian proclivities in the human race, and swells the category of peculiar "college customs" which, like the Indian of the traditional cowboy, are good only after they are dead.

It may be urged that educators constitute a "standing army" in conflict with ignorance. But there is no real analogy between their duties and those of soldiers, firemen and police.<sup>1</sup> Farmers combat the hunger of the community; physicians, disease; lawyers, misapprehension, injustice and crime; clergymen, the ape, bull and tiger in man; and all good citizens are in constant warfare with the undesirable elements of society; but these groups do not proclaim themselves by needless, conspicuous and costly Pharisaic habiliments.

According to the official pamphlet named above the prices of the "hooded gown" for the master's degree range from \$35 to \$85; those for the doctorate, \$10 more. For some classes such an outlay for garments to be worn upon comparatively infrequent occasions might not be excessive. But, until recently, most college professors, excepting such as had independent means or no families, were pleading with reason and commonly in vain for compensation that might enable them to provide for a less productive period of life. Now that the specter of retirement-penury has been exorcised by the bounty of Andrew Carnegie is it any the more becoming in his beneficiaries to indulge in a costly revival of medieval flummery?<sup>2</sup>

<sup>1</sup>It is not denied that occasions might arise when uniforms indicative of ordained pedagogic authority might prove useful in quelling disorder and averting destruction of property as, *e. g.*, at the recently reported *ante factum* football demonstration in the dining hall of a great university; the writer believes, however, that in all such cases a well-disciplined and fully supported fire department would act more appropriately and effectively.

<sup>2</sup>A somewhat comparable condition confronts former officers of the United States Volunteer Army in respect to membership in the "Military Order of the Loyal Legion." The initiation fee

The foregoing considerations are submitted in the hope that reflection upon them may lead some, especially among the younger scientists, to resist the temptation to "follow the fashion." They would better imitate the elder Agassiz; he received many foreign decorations; yet I never saw them displayed or witnessed in his demeanor or dress any feature suggesting a distinction between himself and the average American citizen.

BURT G. WILDER,

*Emeritus professor in Cornell University,  
and formerly surgeon of the  
Fifty-fifth Regiment of Massachusetts  
Volunteer Infantry*

WASHINGTON, D. C.,

November 25, 1912

THE LATE DR. EDWIN TAUSCH

TO THE EDITOR OF SCIENCE: Permit me to call attention to a sad case of the widow and children of a man eminent in science—a case well worthy of charitable help from those who are able or disposed to give. Dr. Edwin Tausch, a young German, graduate in psychology from one of the German universities, was professor in Ohio University at Athens, and afterwards because of failing health, accepted the chair of psychology and philosophy in Willamette University, Salem, Oregon, but was obliged to give up this work on account of heart troubles, and finally during the past is \$35 and the annual dues for residents, \$12. Unlike retired officers of the regular army volunteer officers (unless more or less disabled by wounds or disease) receive from the government only a moderate pension proportionate to their age and length of service. Even this is of real help to many. Probably others besides the writer feel that the essential requirements and objects of the "Loyal Legion," viz., a modest badge, clerical service, and aid to the needy, might be provided for at a far less initial and yearly expenditure, and that conformity to the present scale is burdensome for many and unbecoming the beneficiaries of the nation. I resist the temptation to animadvert upon the showy, complex and cumbersome dress uniform and equipment of army officers as incongruous with the ideal of the professional soldier as a component of an efficient fighting machine.

summer died, leaving a wife and two children almost penniless in Germany. It is almost impossible for Mrs. Tausch to support herself and her children in that country and unless she can do so the children will be placed in an orphanage. It is her wish to find means for herself and her children to return to America where the children were born and where she herself would be able to find work as a teacher. In Germany "hundreds like herself are already waiting for a position wherever there is an opening." Dr. Tausch published a number of valuable papers, notably a sympathetic review of Dr. James's "Pragmatism." A study of the psychology of Tolstoy is still unpublished, as well as an extensive volume on pragmatic philosophy. Should any one feel like granting aid to the widow of this gifted but unfortunate scholar money may be sent through the writer or to Madam Elizabeth Tausch, care Frau von Wissman Warkotsch Kreis, Strehlen, Schlesien, Germany.

LELAND STANFORD JUNIOR UNIVERSITY

#### SCIENTIFIC BOOKS

*The Humble-Bee, its Life History and How to Domesticate it, with Descriptions of All the British Species of Bombus and Psithyrus.* By F. W. L. SLADEN. London, Macmillan & Company, Limited. 1912. Pp. xiii + 283; 6 plates and 33 text figures. \$1.50 net.

This account of the life-history of the humble-bee will be more than welcome to every entomologist and student of animal behavior, not only because it is written by an eminent authority on the honey-bee, but because it is one of those rare nature books that are the mature fruit of a life-long interest and occupation. The author is so intimately acquainted with every detail in the daily and seasonal life of the British humble-bees and its parasites, and handles his subject in such a clever and fascinating manner, that one may fail to appreciate the great amount of patient observation and toilsome experimentation on which his statements are based. With true British independence he refrains from annoy-

ing and confusing the reader with citations of the large and scattered literature of the subject. Almost the only continental work he cites on the habits of the humble-bee is the classic memoir of Hoffer, "Die Hummeln Steiermarks," published thirty years ago (1882). The more recent work of Wladimir Wagner, "Psychobiologische Untersuchungen an Hummeln mit Bezugnahme auf die Frage der Geselligkeit im Tierreiche," *Zoologica*, Heft 46, I. and II., 1906 and 1907, is not even mentioned, and one familiar with this work may be pardoned if he secretly hopes that Sladen has never seen it, not because it is devoid of considerable merit, but because its spirit gives one reason to suspect that Sladen might have become sophisticated by its perusal. There is, indeed, no better way of appreciating the English author's work than by following it with a perusal of Wagner. Both authors have independently discovered and described a number of important peculiarities in humble-bee life that were unknown to Hoffer, but how different is the view-point from which their observations are made! In Sladen's work the humble-bee is the heroine of the story. She moves before us in all the glory of her regal, velvety attire, with the joyous or apprehensive hum of incessant, arduous labor and self-sacrificing motherhood. In Wagner's account it is Wladimir Wagner who occupies the foreground as the somewhat bumptious scientist who looks at the humble-bee, makes an observation, forthwith settles its connection with some lop-sided hypothesis, incidentally belabors a few contrary-minded, or bestows his approval on a few like-minded students of animal behavior, and then repeats the process. Sladen, on the other hand, writes with charming, sympathetic insight, and utterly unmindful of committing one of the most deadly sins that it is possible for a modern student of animal behavior to commit, pens such sentences as the following, in which the italics are the reviewer's: "The queen's *intelligence* is seen at its best while she is thus *caring* for her brood, and her *devotion* to it, and her *alertness* on the slightest approach of danger, are most interesting to witness. She shows

no *desire* to escape unless she is severely molested and is quite *content* with her brood, *anxiously* incubating it day and night." This is the way Wagner, who is beset with a terrible anxiety lest he commit this deadly sin of "grober Anthropomorphismus," describes the behavior of the same insect: "Eine nicht weniger auffallende Erscheinung ist der Versuch der Hummel, das Nest auszubessern. Erregt durch das eindringende Licht, steigt sie von der Wabe auf den Boden herab und kriecht rückwärts zu derselben zurück, wobei sie die bei solchen Gelegenheiten üblichen Bewegungen des 'Zusammenscharrens' trockener Pflanzenteile ausführt, d. h. nicht nur Bewegungen macht, deren Bedeutung sie nicht versteht, sondern nicht einmal im stande ist, auch nur die geringsten Resultate ihrer Tätigkeit wahrzunehmen, welche sie nur aus dem Grunde ausübt, weil diese Tätigkeit eine Reaktion auf die Gesamtheit der äusseren Reize darstellt." Surely, if we may ask Sladen how he knows that the humble-bee experiences anything akin to the affection and solicitude of the human mother for her offspring, we may also ask Wagner how he knows that such a highly organized insect as the humble-bee is a mere machine and absolutely unable to appreciate the results of any of her activities. Such quotations reveal the difference between Sladen's and Wagner's methods of observation and incidentally between the two schools of animal behavior which they represent. To one the insect is a wonderful and inexhaustible living organism, whose activities can be most satisfactorily described in the language which we employ when speaking of another individual of our own species; to the other the insect is a pure mechanism, whose every movement is easily expounded by the observer, who stands in the foreground and uses the observed object largely as a means of displaying his own analytical and explanatory acumen. The student of animal behavior, who wishes to appreciate the merits and defects of each of these methods, can hardly do better than to read in close sequence Sladen's and Wagner's memoirs on the humble-bee.

Sladen's book begins with a brief introductory chapter on humble-bees in general, their geographical distribution, their relations to flowers and their more important external characters. This is followed by a beautiful account of the life-history of the British species, with excellent figures of their nests, illustrating the behavior of the queen in establishing the colony, and the growth and arrangement of the brood-comb and of the honey- and pollen-pots. The author's interesting and original classification of the British *Bombi* as "pollen-storers" (*B. lapidarius*, *terrestris*, *lucorum*, *soroënsis*, *pratorum*, *jonellus*, *lapponicus* and *cullumanus*) and "pocket-makers," which are subdivided into "pollen-primers" (*B. ruderatus*, *hortorum*, *latreillellus* and *distinguendus*) and "carder-bees" (*B. deshamellus*, *sylvarum*, *agrorum*, *helferanus* and *muscorum*) is described and illustrated in detail. The third chapter, devoted to the "usurper bees" of the genus *Psithyrus*, carries us well beyond the researches of Hoffer and gives us the complete life-history of these extraordinary parasites. As ascertained by Sladen, this life history resembles in the most striking and suggestive manner that of certain parasitic ants of the genera *Polyergus* and *Bothriomyrmex*, since the female *Psithyrus* usurps the position of the *Bombus* queen by killing her and securing adoption by her workers, which then assist the parasite in bringing up her brood.

The fourth chapter takes up the other *Bombus* parasites and enemies. These constitute a very large and motley assemblage of organisms, including the meadow mice, a peculiar wax-moth (*Aphomia sociella*) which devours not only the cells, but also the brood of the humble-bee, a Tachinid fly (*Brachycoma devia*), the highly mimetic *Volucella bombylans*, besides several other Diptera belonging to the genera *Fannia*, *Phora*, *Conops*, etc., several Hymenoptera, especially *Mutilla europæa*, certain Braconids and ants, more than 50 species of Coleoptera, among which *Antherophagus nigricornis*, a small beetle that is carried from the flowers, into the nests attached by its mandibles to the proboscis of the bee, is one of the most interesting, several

mites, a singular Nematode worm, *Sphaerularia bombi*, which lives in the abdomen of the queen, and a Microsporidian belonging to the genus *Nosema* and allied to the *N. apis* recently shown to be the cause of the "Isle of Wight disease" of the honey-bee. Several of these parasites may simultaneously attack a colony of humble-bees and completely destroy it in a very short time. The reviewer, on August 18, 1909, found under a stone at Zermatt, Switzerland, a small alpine humble-bees' colony which had been utterly wiped out by no less than three of these parasites. The cells and brood had been devoured by a mass of wax-moth larvæ (*Aphomia*) which were nearly ready to pupate. Among these lay a number of puparia of the Tachinid *Brachycoma*, while perched on the top of the nest among four dead and dying humble-bees was a fine female *Mutilla europæa*. It is certainly remarkable that notwithstanding the inroads of all these parasites and predators and the small size of the colonies compared with those of many other social insects, the humble-bees, nevertheless, manage not only to survive, but to maintain their position among the commonest insects of the north temperate zone. And this dominance of the genus *Bombus* is even more surprising when we stop to consider that its species very easily succumb to excessive moisture, especially in countries like Great Britain.

Chapters V. to VII. of Sladen's work treat of the practical methods of studying the humble-bees, of finding and taking their nests, of the construction of artificial or observation hives, and of attracting to the latter the overwintered queens. In these chapters, which show how Sladen acquired his intimate knowledge of humble-bee behavior, we can also detect the advantages he has secured from his practical study of the honey-bee. By "domestication" he means merely the bringing of the humble-bee into the same relations to man as those obtaining in the case of the honey-bee. In the proper sense of the term, of course, neither of these insects can be domesticated.

The eighth chapter of the work is devoted

to the taxonomy of the British humble-bees and is illustrated by five fine colored plates, showing the males and females, and a plate of line-drawings, showing the male genitalia, of the 17 species of *Bombus* and six species of *Psithyrus* known to occur in Great Britain. The work concludes with a short chapter on making a collection of humble-bees, one containing a number of interesting notes and anecdotes and a brief appendix with some additional miscellaneous observations. It is certain that this volume will long remain a classic and an inspiration not only to British students of humble-bees, but to many of our entomologists, whom its perusal should encourage to acquire an equally intimate knowledge of the practically all but unknown habits of the numerous North American *Bombi*.

W. M. WHEELER

*The Snakes of South Africa: Their Venom and the Treatment of Snake Bite.* By F. W. FITZSIMONS. With 193 figures, mostly original photographs. New edition. Cape Town and Pretoria, T. Mashew Miller; New York, Longmans, Green & Company. Pp. xvi + 547.

This book is a natural history of South African snakes that, while written in a popular way and primarily for South Africans, and mainly devoted to the relations of the poisonous species to man, deserves to be brought to the attention of students of herpetology. The writer attempts to acquaint the residents of South Africa with the general habits of the snakes of their region, and to point out to the general reader, in simple language, the possibilities of being bitten by a poisonous snake, the action of the venom, and the best treatment that the investigators of the nature of snake venom have worked out.

As the principal aim of the book is thus to educate the non-scientific readers in a region where venomous snakes abound, one can not quarrel with the author for devoting considerable space to the poisonous species, even though his only original contributions to this subject are the results of investigations of the toxicity of the South African species. There

is nothing of interest to the student of herpetology in the first two chapters, on the classification, evolution, history, distribution, general habits and identification of species of snakes, and the chapter on snake charmers, Kafir superstitions, etc., and the one on human physiology may also be ignored.

On the other hand, the herpetologist will find much of interest in the accounts of the habits of different species. The writer is evidently a careful field observer, and his descriptions of the feeding and breeding habits of certain forms are a distinct contribution. For example, the description of the feeding habits of the puff adder (p. 225) could hardly be improved. A very notable feature also is the numerous photographs of snakes, both in their natural haunts and in captivity. The series showing a specimen of *Dasyplis scabra* eating an egg and ejecting the shell, and the photographs of the mole snake, ringhals cobra, and puff adder with newly born young are notable, and there are many others of equal interest. There is also a considerable amount of information on the habitat preferences of various forms that will be useful.

The author is to be commended for the care exercised in guarding against the errors that are so liable to occur in a popular account. The word skin is rather loosely used for the stratum corneum in the account of sloughing (p. 16); snakes do frequently eat dead animals in nature (p. 40); it is doubtful if many naturalists still hold the opinion that the fangs of opisthoglyphs are primarily for holding the prey (p. 139); and the toad is not a reptile (p. 227). It is rather surprising that the writer advocates sucking the wound made by the bite of a venomous snake, since this is dangerous unless one is sure that there are no abrasions about the mouth, and Noguchi asserts that the procedure is quite useless. It may be added that the author's style is rather tautological, there is some irrelevant matter, and a closer grouping of the subject matter would be advantageous.

The reviewer would suggest that an easy key to the South African species would much increase the value of the book. It is doubtful

if many persons would take the trouble to dissect out the jaws to identify the species; at any rate it would not be easy to use the author's key, scattered as it is over several chapters.

ALEXANDER G. RUTHVEN

MUSEUM OF NATURAL HISTORY,  
UNIVERSITY OF MICHIGAN

*General Physics.* By W. WATSON, F.R.S.  
Longmans, Green & Co. 564 pages, with 311 figures and diagrams.

It is a very interesting fact that Professor Watson, who has given to us the comprehensive "Text-book of Physics" with its nine hundred and fifty pages, should find it necessary to arrange another text to meet the needs of "engineering, medical and other students." Not only has he condensed and rearranged his larger work, he has placed the emphasis on different topics and has omitted many. Among these may be noted the discussion of the energetics of a voltaic cell and that of Maxwell's electromagnetic theory. Fifty pages in the older text are given to electrolysis and electric cells where only sixteen are required in the new text. The three hundred pages given to electricity and magnetism in the older text have here been cut in half, notwithstanding the fact that much new matter is added on account of the discussion of radio-activity and wireless telegraphy.

It is rather probable that the newer text will suit the needs of a larger number of instructors in general physics in American colleges than did the older text. For it can be said that the table of contents includes all the main essential principles of physics with a reasonable number of applications to the affairs of every-day life. The presentation is direct, matter of fact, concise, clear. There is no time or space for the spectacular or ornate. The author, being an Englishman, does not give an explanation, right or wrong, of the curving of a base ball, nor of a tennis ball—though had he done so he might have claimed that he was but following the example set by the illustrious Newton. Nor is the mono-rail car discussed. But in America

these omissions are not as serious as they are in England, for here one can probably find them discussed in the Sunday editions of the daily papers!

There are some omissions, however. In the chapter on radiation no mention is made of the sensitive instruments for detecting and measuring radiant energy—the thermoelement, the radiometer, the bolometer. In fact, the discussion of radiation is rather inadequate. In the chapter on the interference of light several pages are given to the discussion of Fresnel's mirrors and biprism, but no mention is made of the interferometer, although the latter is as important theoretically as the former and vastly more important in its numerous applications to exact measurement.

In the chapters devoted to heat, however, admirable illustrations of the application of the principles to modern heat engines are given. In electricity, too, the points of contact of the subject with the world of to-day are shown.

In a book where so much material is presented in so few pages the method of approach is abrupt and the style at times uninteresting. The text will not find favor with those teachers who place emphasis on the inductive aspect of the science nor will it be pleasing to those students who look for entertainment in their reading, but it is a very dependable, clear and fairly complete statement of the principles of physics.

G. F. HULL

DARTMOUTH COLLEGE

### *Essentials of Physics for College Students.*

A Text-book for Undergraduates and a Lecture Course and Reference Work for Teachers and Other Students of Physics. By DANIEL W. HERING. The D. Van Nostrand Co. 353 pages, with 166 illustrations.

The author tells us in the preface that the work is the outgrowth of a course of lectures which he has delivered for several years past to undergraduate students, and that it is intended for that class of students preparing to fill the position of educated men and women who are not specialists in science. As the

contents of the book are intended to be presented in "sixty lectures of fifty minutes each" some rather important, perhaps essential, parts of the subject have received a very brief description. On the other hand, liberal space is given to some pseudo-philosophic topics. One notes that the author gives only two pages to the presentation and discussion of the mechanical equivalent of heat and the laws of thermodynamics. The connection between the absorbing and reflecting power of surfaces is given in two lines. But notwithstanding this brevity the author devotes the larger part of the first twelve pages to these captions or questions: Physics, is it or is it not a study of matter, ether and motion? Why study physics? Space, time, matter; Energy "a capability of matter." The best feature in this discussion is found in the definitions and statements quoted from Maxwell's "Matter and Motion."

A couple of pages are given to the discussion of *inertia* in which the author decides that one can no more measure the quantity of matter by its inertia than one can measure the size of a dead elephant by its deadness. This adherence to the notion that *inertia* is a property of matter which can not be represented quantitatively is not in accord with the custom of physicists. The terms *inertia* and *moment of inertia* are used quantitatively in physics. Such authors as Crew and Ames set forth in a very clear manner the mode of measuring the quantity of a bit of matter by its inertia or reluctance to change of linear motion. The author does not deal with the large topic of rotational motion, consequently he makes no reference to *moment of inertia*.

In dealing with the units involved in force and work the author brings in the engineer's system (footnote, p. 32): "If force be measured in pounds then the mass will be in pounds  $\div 32$  and work will be in foot-pounds." Had the equation of force been written  $F = kma$  instead of  $F = ma$  there would have been no necessity for this statement and the confusion it brings to students would have been avoided.

Apart from these criticisms the text is to

be commended for the clearness with which physical principles are stated, and for the numerous workable and practical problems. That part of the text dealing with lenses and with problems concerning the eye is especially to be commended.

One feature of the text which distinguishes it from others is the grouping together of descriptions of demonstration experiments at the end of each chapter. This is a matter of considerable convenience to an instructor and should prove interesting to a student. Another commendable feature is the large number of references to, or quotations from, other texts or original articles.

The author apparently has not attempted to condense as great a number of facts and principles as possible into the text, but has attempted to present in an interesting form what appears to him to be of most importance, and he has succeeded. As a piece of book-making the text is excellent.

#### SPECIAL ARTICLES

##### THE NUTRITIVE VALUE OF THE PROTEINS OF MAIZE

The state of knowledge at present prevailing concerning the nutritive value of cornmeal when fed to domestic animals is clearly presented in a letter which I recently received from Professor Willard, of the Kansas Agricultural College, who has had a wide experience with practical feeding experiments made on a large scale on domestic animals. He says:

It is a matter of common experience extending over many years, that corn appears to be deficient in some particular in nutritive value. Some have thought to account for this on the basis of low protein content; others have attributed the result to its small percentage of ash; still others have taken into account not only the small percentage of ash, but its unbalanced character, being deficient in calcium and possessing a large percentage of magnesium; still more recently there has appeared the possibility that the defect may find an

explanation in limitations in the amino-acid components present in the corn protein.

From this quotation it is evident that further study is needed in respect to the relative nutritive value of the constituents of this seed. Professor Mendel and I have recently obtained preliminary results from feeding maize proteins to white rats under conditions similar to those which I described at our fall meeting last year.

The proteins of maize have not received the attention that their great economic importance demands, for these, the most valuable constituents of this seed, form from eight to ten per cent. of a crop which in this country alone is annually worth one and a half billion dollars. This is the more remarkable as those chemical investigations which have been made show that at least one half of the protein of this seed consists of a type possessing such unique chemical and physical characters as to make it probable that its nutritive properties differ to a marked extent from those of the proteins in other foods of either vegetable or animal origin.

In addition to this protein, known as zein, the maize kernel contains small quantities of globulins, albumins and proteoses and also protein substance insoluble in neutral solvents which can be extracted from this seed only by dilute alkalis. This latter protein has been named maize glutelin. According to such data as are at present available, zein forms about 58 per cent. of the proteins of corn, the globulins, albumins, and proteoses together about 6 per cent., and the remaining 36 per cent. is supposed to be maize glutelin.

The few recorded attempts to determine the nutritive value of maize proteins, in the isolated state, have been made only with zein. The conditions under which these have been conducted have been such as to render the results of uncertain value, although in every instance zein, when supplied as the only protein, proved ineffective for maintaining adult animals or promoting the growth of the young.

Zein presents striking differences in its amino-acid make-up when compared with the other proteins commonly present in foods. The greatest interest has centered about the

<sup>1</sup> Read before the National Academy, November 13, 1912.

entire absence of tryptophane and lysine, for feeding experiments with zein were expected to shed light on the important question of amino-acid synthesis by the animal.

Maize glutelin, in contrast to zein, yields all of the amino-acids commonly found in proteins and in proportions corresponding to those yielded by the majority of animal or vegetable proteins.

The globulins, albumins, and proteoses occur in such small quantities that it has not been possible to obtain them in sufficient amount to determine their amino-acid makeup, or their value in nutrition.

and food intake, broken line, of several rats fed on our protein-free milk diet.<sup>2</sup> During period 2 all of these rats had a diet containing zein as its sole protein and, as you will note, they rapidly declined in weight, although the food intake remained nearly constant, or was even increased, as shown by rats 617 and 647. That this quantity of food was sufficient for maintenance is shown by rats 628 and 659, which regained part of their lost weight on an even smaller quantity of food after the zein had been replaced by gliadin. The increased food intake when zein was replaced by casein, edestin or lactalbumin is largely to be ascribed

CHART I

Last fall the results of two experiments with mature rats supplied with food containing zein as its sole protein were described. In both cases the animals declined rapidly in weight, although their food intake remained practically constant. These results have since been confirmed by a large number of experiments, some of which are illustrated by the following charts.

Chart I. shows the body weight, solid line,

to the rapid gain in weight which took place when this change was made in the ration. It might be thought that a failure to digest and assimilate zein was the cause of the decline on the zein diet, but curves which you will see later show that can not be so, for the addition of a small amount of tryptophane renders the

<sup>2</sup> SCIENCE, N. S., Vol. XXXIV., No. 882, pp. 722-733, November 24, 1911.

zein food efficient for maintenance over a long period.

Our experiments show that there is a very great difference in the food value of different proteins. Thus we have complete nutritive failure with zein, maintenance with gliadin, and restoration of lost weight, or normal growth, with either casein, lactalbumin or

which is still in progress, indicates that the failure to grow, shown by rat 593, or by rats fed with gliadin, is not due to a lack of lysine in the protein. The fall in weight shown by these two rats at the beginning of the experiment is probably chiefly due to the less bulky experimental food, and the consequent smaller quantity of feces in the digestive tract.

CHART II

edestin. These three latter proteins yield on hydrolysis both tryptophane and lysine, which zein lacks, whereas gliadin, which is incapable of promoting growth, yields tryptophane, but only a very insignificant proportion of lysine. Gliadin resembles zein in the proportion of amino-acids, other than tryptophane, but differs widely from casein, lactalbumin or edestin.

Chart II. shows that when a quantity of tryptophane corresponding to 3 per cent. of the protein is added to the zein food, the rat does not decline in weight, but is maintained without growth, just as if fed with gliadin. The curve for rat 892 likewise shows maintenance without growth. This experiment,

Charts I. and II. show that zein is incapable of maintaining rats, unless tryptophane is added to the diet, whereas on the other proteins, all of which yield tryptophane, they recover their lost weight, and grow at a normal rate except on gliadin. This raises the question whether or not the replacement of a part of the zein by other proteins containing tryptophane will render the ration effective in promoting growth. Unfortunately there is no method known whereby the amount of tryptophane in a protein can be even approximately determined. The nearest approach to an estimate of the relative amount is given by a comparison of the intensity of the color shown by the glyoxylic acid reaction. Such a compari-

son indicates that lactalbumin yields much more tryptophane than edestin, and that edestin yields somewhat more than casein or gliadin, which give reactions of about equal intensity.

We have made some preliminary experiments to determine the effect of replacing a part of the zein with other proteins, but these have not been continued long enough to give final conclusions. The three upper curves show that when one third of the zein is replaced by casein, edestin or gliadin the rat rapidly loses weight. The fall is less rapid and less extensive when one third of the zein is replaced by edestin than when it is replaced by casein.

Chart I., rat 634, shows that when one fourth of the zein is replaced by lactalbumin, weight is regained. Unfortunately this experiment was terminated by death from diseased lungs.

Chart III. shows that rat 633 regained its lost weight very rapidly when one half or one

So far as these results go they agree with the relative intensity of the glyoxylic acid reaction for tryptophane.

Chart IV. shows complete recovery of lost weight when one half of the zein was replaced by casein, and rapid decline when the proportion of casein was reduced to one sixth. This decline was at once stopped when tryptophane was added to the food, the proportion of zein and casein remaining the same. The last period of this experiment was unsatisfactory as the rat soon after died with diseased lungs and kidneys. If disease had not intervened it is not improbable that the lost weight would have been fully regained in period 4.

Chart V. shows a rapid loss of weight when zein formed the sole protein of the diet, and complete recovery when one half of the zein was replaced by casein. After being again reduced on the zein diet, a partial recovery was made when one half of the zein was replaced by edestin, and a nearly complete recovery, when all was replaced by edestin.

CHART III

quarter of the zein was replaced by lactalbumin. Rat 487 regained its loss more slowly with one half edestin. Rat 644 was maintained by one half gliadin, and declined rapidly and died when changed to a diet containing one half zein and one half gelatin, a protein which like zein lacks tryptophane.

It is difficult to understand why diets containing two thirds zein and one third casein or edestin are so inferior to those containing one half of either of these proteins. It may be that experiments now in progress will not confirm these preliminary results, but it is also possible that we shall find that a certain min-

imal quantity of tryptophane is essential for life, and that this is not supplied by these smaller proportions of casein or edestin.

Thus far the experiments I have described have been concerned with zein, which is only one of the proteins of maize.

formed the sole protein. On this diet the rat quadrupled its weight in 70 days, thus exceeding somewhat the average normal rate of growth of rats on natural mixed food. Rat 596 grew more slowly on a diet containing equal parts of zein and maize glutelin.

CHART IV

CHART V

Chart VI. shows that corn contains a protein which is capable of promoting normal growth. During period 2, rat 567 was fed with a diet containing the same non-protein constituents as those used in the preceding experiments, but in this food maize glutelin

Chart VII. shows the result of feeding rats with corn gluten. This substance is a product obtained in the manufacture of corn starch, and consists chiefly of zein and maize glutelin, which are separated from the corn by purely mechanical operations. With this

material we have an opportunity to study the nutritive value of the proteins before they have been subjected to the chemical operations incident to their isolation and purification. These curves show that the mixture of proteins in the corn gluten is capable of maintaining

imals. It is interesting to note that the weight lost by these animals was much more quickly regained when one half of the corn gluten was replaced by lactalbumin than by edestin, results which agree with those obtained by adding these proteins to the zein diets.

CHART VI

CHART VII

rats for some time. Unfortunately at the time these experiments were started our supply of stock rats was so low we were obliged to use rats which had been previously subjected to long-continued experimental feeding. Doubtless better results will be obtained when we repeat these experiments with fresh ani-

The results here presented leave no doubt that the deficiency observed in the practical feeding of cornmeal is explained largely, if not wholly, by the unique chemical constitution of zein which forms such a large part of its proteins.

Many more experiments must be made be-

fore the numerous questions raised by our feeding trials can be regarded as settled, and attention must finally be given to the relative food value of mixtures of various food stuffs with corn meal, so that we may know as definitely as possible the most economical combinations to employ in maintaining mature animals and in raising the young. Such experiments must be conducted on a large scale and with a variety of domestic animals. In carrying these out the results obtained by the method I have just described when combined with the experience gained in feeding animals for market will doubtless lead to a lower cost of meat production, and at the same time give us information which will contribute to a clearer understanding of some of the obscure problems of the chemical physiology of nutrition.

THOMAS B. OSBORNE

CONNECTICUT AGRICULTURAL  
EXPERIMENT STATION,  
NEW HAVEN, CONN.

#### DISCOVERY OF BIVALVE CRUSTACEA IN THE COAL MEASURES NEAR PAWTUCKET, R. I.

WHILE collecting fossils for the Museum of Comparative Zoology, Cambridge, from the Carboniferous graphitic slates of Central Falls, Rhode Island, last June, the writer discovered in a half inch layer at two localities one hundred yards apart about two dozen, more or less well preserved impressions of carapaces of bivalve crustacea of the genera *Leaia* and *Estheria*, in the same layer with numerous plant impressions, chiefly leaves of Cordaites and Calamites. No record of their having been previously discovered in the Narragansett Basin Coal Measures was found by the writer, and no specimens of any bivalve crustacea occur in the collection of Coal Measure material from the basin, at Brown University or at Harvard.

The faunal remains from the Narragansett Basin Coal Measures are comparatively meager, and consist largely of tracks which are in many cases of doubtful determination. Previous to the year 1900, fourteen species of insects and one arachnid were identified by Scudder,<sup>1</sup> and the tracks of a probable annelid and of a mollusc or worm were described.<sup>2</sup> In 1900 A. S. Packard<sup>3</sup> described some prob-

able worm tracks, and those of a possible crustacean which were found in some red shale boulders at South Attleboro. He described and named another track found in a pebble of arenaceous shale in a kame in North Providence, and three fragments of a possible macrurous crustacean from the black shales of Valley Falls, R. I., and noted a locality near East Attleboro, shown to him by Professor J. B. Woodworth, where sand-filled worm borings occur in the red and green shales. He also described and identified several casts of valves of a fresh-water mollusc *Anthracomya arenacea* (Dawson) Hind, from a boulder of fine black shale at Valley Falls, and one specimen from a shale bed north of Silver Spring, East Providence.

Numerous supposed amphibian tracks have been found by Professor J. B. Woodworth near Plainville, Mass., and one species, *Batrachichnus plainvillensis*, has been described<sup>4</sup> and named by him. Since then he and the writer have found many types of tracks from several localities near Plainville, and these will probably be described in detail soon. Two or three tracks of probable amphibia were found by Professor Woodworth and the writer last June at Valley Falls and Central Falls, R. I., which is very much south of the localities where they have been previously noted.

From this brief summary of the occurrence of the fossil fauna, it will be seen that only a part of the specimens have been found *in situ*, and the majority of these are tracks. The discovery of these bivalve crustacea in place is therefore of considerable importance.

The impressions of the valves of *Leaia* and *Estheria* occur in a grayish black, somewhat graphitic slate bed along the south bank of the Blackstone River in Central Falls, R. I. The beds strike N. 70°-80° E. about parallel with the river at this place, and dip 70° N.

<sup>1</sup> Bull. U. S. Geol. Survey, No. 101, 1893.

<sup>2</sup> *Proc. Bost. Soc. Nat. Hist.*, XXIV., 1889, pp. 209-216, and *Amer. Jour. Sci.*, 3d Ser., XXXVII., 1889, p. 411.

<sup>3</sup> *Amer. Acad. Arts and Sci. Proc.*, Vol. XXXV., 1900, pp. 399-405.

<sup>4</sup> *Geol. Soc. Am. Bull.*, Vol. IX., 1900, pp. 449-454.

The section consists of alternating slate and gray sandstone layers, of a few feet thickness. The slate usually has numerous fossil plant impressions in it, but the sandstone here is barren of recognizable organic remains.

The specimens of the genus *Leaia* Jones, are in general well preserved and show the surface markings distinctly (see Fig. 1).

Fig. 1. X2.

Fig. 2. X2.

They correspond closely with the description and figures of *Leaia tricarinata* Meek and Worthen,<sup>5</sup> of the Illinois and Indiana Coal Measures. The size of an average specimen from Rhode Island is: length, 8.5 mm.; height, 5 mm. The presence of a well-marked third carina along the dorsal margin and the twelve to sixteen slender concentric ridges, as well as the agreement in size, make it seem safe to call the Rhode Island specimens *Leaia tricarinata*.

Several specimens of the genus *Estheria* Ruppel occur in the same layer with *Leaia* (see Fig. 2). They vary slightly in size and proportions, but all show the generic characters well. The surface markings are not as distinct as in the specimens of *L. tricarinata*, but most of the *Estheria* specimens show from nine to thirteen faint concentric striae. The size of an average specimen from Rhode Island is: length, 7 mm.; height, 5 mm. The specimens are not sufficiently well preserved to permit of a specific determination.

In the Conemaugh Series of the Carboniferous of Pennsylvania, Dr. P. E. Raymond<sup>6</sup> has noted the presence of *Estheria* and *Leaia tricarinata*, with plant remains, in a red and gray shale layer occurring just below the Ames limestone, which is midway in the Conemaugh Series. Fossils of the two genera occur in several horizons of the Coal Measures. In Illinois *L. tricarinata* ranges from the

lower part of the Lower True Coal Measures, to high up in the Upper Coal Measures, therefore neither genus is a good horizon marker. If we regard the *Estheria*, *L. tricarinata* horizon of the Conemaugh Series as of the same age as that at Central Falls, R. I., we should then be calling this horizon of the Narragansett Basin Series the equivalent of the middle of the Lower Barren Measures of Middle Pennsylvanian age.

WINTHROP P. HAYNES

CAMBRIDGE, MASS.,

October, 1912

#### THE ELECTROMOTIVE FORCE PRODUCED BY THE ACCELERATION OF CONDUCTORS

THE possibility that electromotive forces may be produced by the mechanical acceleration of electric conductors was first thoroughly considered by Maxwell,<sup>1</sup> and the actual presence of such electromotive forces in *electrolytic* conductors was shown by Colley<sup>2</sup> in 1882.

The desirability of obtaining similar electromotive forces in accelerated *metallic* conductors has long been recognized by the writer. At a meeting of the Harvard and Massachusetts Institute of Technology Physical Chemical Society, held at the Harvard Union in the spring of 1906, he stated that a potential difference was to be expected between the front and rear ends of a metallic conductor which is suddenly stopped, since there will be a tendency for the electrons to continue in motion. Since that time he has often spoken to his colleagues, both privately and at informal scientific meetings, of the desirability of making measurements of this kind in order to obtain information as to the mass of the carrier in metals, and in particular has described as a possible form of apparatus a coil of wire oscillating about its own axis with some form of commutator to permit the detection with an ordinary galvanometer of the alternating current which would be generated.

During the past year at the University of Cincinnati, with the help of his assistant, Mr. Earl W. Osgerby, the writer has carried out

<sup>5</sup> *Geol. Surv. Ill.*, Vol. 3, pp. 541-543.

<sup>6</sup> *Ann. Carnegie Mus.*, Vol. V., No. 2 and 3, 1909, p. 173.

<sup>1</sup> Maxwell, "Treatise on Electricity and Magnetism," 3d edition (1892), Vol. II., 211 et seq.

<sup>2</sup> Colley, *Wied. Ann.*, 17, p. 55, 1882.

an elaborate series of measurements on the electromotive forces produced by the acceleration of electrolytes, varying the nature of the solutions used, the magnitude of the acceleration, and the distance between the front and rear electrodes, and is now preparing for publication a description of the work. The experiments were performed, however, primarily as a preliminary to similar work with metals in order to test the quantitative theory as to the magnitude of the effect which would be much larger in electrolytes than in metals, and in order to determine the most suitable form of apparatus for the work. Mr. Osgerby and the writer did, however, carry out some experiments with metallic conductors, but at the time were unable to detect any effect, as further modification of the apparatus is necessary before it will be sensitive enough for metals.

In a recent number of SCIENCE (November 1, 1912) the writer was surprised to observe that Professor Daniel E. Comstock, of the Massachusetts Institute of Technology, has not only apparently attempted to reserve this field of experimental investigation, but to put forward as a new discovery the probability that such electromotive forces would be produced by the acceleration of metallic conductors. The possibility of such electromotive forces has certainly been recognized since the time of Maxwell. In *electrolytic* conductors their actual presence has been shown by the experiments of Colley, and the similar electromotive forces which arise from the action of centrifugal force on electrolytic conductors were demonstrated by Des Coudres<sup>3</sup> and have been thoroughly investigated by the present writer.<sup>4</sup> In another, to obtain effects dependent on the *metallic conductors* Maxwell,<sup>5</sup> Lodge,<sup>6</sup> and Nichols<sup>7</sup> have all attempted, by one method or

another, to obtain effects dependent on the "mechanical momentum" accompanying the passage of electricity, but have failed, owing to the lack of sensitiveness of their apparatus. That the conception of "free electrons" necessarily includes the production of an electromotive force in accelerated metals is certainly the common knowledge of physicists who are familiar with the work of the above investigators.

The writer has no desire to reserve a field which is the property of all physicists, but at the present time wishes to report that his experiments are sufficient to show, as would be expected, that the electromotive force produced in accelerated metals is certainly much smaller than that produced in accelerated electrolytes, and to state that the apparatus is now being improved with the hope of detecting the effect in metals.

RICHARD C. TOLMAN

UNIVERSITY OF CALIFORNIA,

November 9, 1912

---

THE AMERICAN SOCIETY FOR PHARMACOLOGY AND EXPERIMENTAL THERAPEUTICS

THE fourth annual meeting of the society was held in Cleveland on December 30 and 31. There were two executive and three scientific sessions.

The most important outcome of the Cleveland meeting, as far as the Pharmacological, Physiological and Biochemical Societies are concerned, was the formation of a federation designed to knit these societies more closely together, while yet jealously preserving the individuality of each component. The meeting of delegates with full power to act from each of the three societies, took place during the last informal dinner and smoker at the Colonial Hotel on December 31. The delegates from the Physiological Society were Drs. Meltzer, Lee and Cannon; from the Biochemical Society, Drs. Lusk and Wells; from the Pharmacological Society, Drs. Sollmann, Loevenhart and Auer.

Dr. Meltzer was elected temporary chairman and Dr. Cannon temporary secretary. The outcome of the proceedings of this conference committee will be best shown by a transcript of its minutes:

"The following motions were voted unanimously:

"That a federation of the three societies be hereby established.

<sup>3</sup> Des Coudres, *Wied. Ann.*, 49, p. 284, 1893; *ibid.*, 57, p. 232, 1896.

<sup>4</sup> Tolman, *Proc. Amer. Acad.*, 46, p. 109, 1910; *J. Amer. Chem. Soc.*, 33, p. 121, 1911.

<sup>5</sup> Maxwell, *loc. cit.*

<sup>6</sup> Lodge, "Modern Views of Electricity," 3d edition (1907), p. 89.

<sup>7</sup> Nichols, *Physik. Z.*, 7, p. 640, 1906.

"That the presidents and the secretaries of the constituent societies form the executive committee of the federation.

"That the chairmanship of the executive committee be held in turn by the presidents of the constituent societies who shall succeed one another annually in the order of seniority of the societies (physiological, biochemical and pharmacological).

"That the secretary of the executive committee shall be secretary of the society whose president is chairman.

"That the secretaries of the three societies shall consult in preparing the programs of the annual meeting, and that, as far as practicable, and with the author's consent, papers be so distributed as to be read to the society in which they properly belong.

"That the programs of the three societies be published by the secretary of the federation under one cover and that the expense of publication be shared *pro rata* by the societies according to the number of members.

"That the official title of the new organization be 'The Federation of American Societies for Experimental Biology' (comprising the American Physiological Society, the American Society of Biological Chemists, and the American Society for Pharmacology and Experimental Therapeutics).

"That a common meeting place of the federation with the Anatomists, Zoologists and Naturalists is desirable but not mandatory.

"That in the name of the federation, the International Physiological Congress be invited to meet in the United States in 1916.

"That the present conference committee delegate all its powers to the executive committee of the federation.

"The meeting then adjourned."

The first meeting of the new federation will be held next December in Philadelphia.

The scientific program was as follows:

#### FIRST SESSION

Monday, December 30, 9:00 to 12:00 M.

Wm. Salant: "The Influence of Temperature on the Toxicity of Caffein." Read by title.

Wm. Salant: "Further Observation on the Influence of Caffein on the Circulation." Read by title.

S. P. Beebe and Eleanor Van Alstyne: "The Effect of High Protein Diet on the Growth of Transplantable Tumors of the White Rat."

Lafayette B. Mendel and R. L. Kahn: "The Physiological Action of some Methyl Purines."

J. A. Eyster and W. J. Meek: "The Action of Certain Drugs on the Electrocardiogram."

Paul J. Hanzlik (by invitation): "The Intestinal Absorption of Alcohol."

Paul J. Hanzlik (by invitation): "The 'Toxic Dose' of Salicylates according to Clinical Statistics."

W. H. Brown and A. S. Loevenhart: "The Effect of Hematin upon the Circulation and Respiration."

Wm. De B. MacNider: "The Effect of Anesthetics on the Output of Urine in Uranium Nephritis."

George B. Roth: "The Physiological Assay of Aconitin."

#### SECOND SESSION

Monday, December 30, 2:00 P.M.

L. G. Rowntree and R. Fitz: "Renal Function in Experimental Passive Congestion."

R. Fitz and L. G. Rowntree: "The Effect of Temporary Occlusion of Renal Circulation on Renal Function."

Wm. W. Ford: "Observations on Three Poisonous Fungi not Previously Described."

J. D. Pilcher: "The Protective Action of Lipoids against Hemolysis."

Henry G. Barbour (by invitation): "The Action of Histamin upon Surviving Arteries."

George W. Crile and J. B. Austin: "Nitrous Oxide Sleep compared with Normal Sleep—Brain Cell Studies."

Wm. T. Porter and J. H. Pratt: "The Action of Diphtheria Toxin on the Vasomotor Center."

Hideyo Noguchi and J. Bronfenbrenner: "The Effects of certain Disinfectants and Therapeutic Preparations upon the Cultivated Spirochaetes." Read by title.

Frank M. Surface (by invitation): "The Effect of Surplus Cow Serum on Complement Fixation with Infectious Abortion."

I. Adler and C. L. Alsberg: "Studies upon the Long-continued Administration of Adrenalin and Nicotin." Read by title.

C. L. Alsberg: "The Hemolytic Power of Various Plants." Read by title.

#### THIRD SESSION

Tuesday, December 31, 9:00 to 12:00 M.

Yandell Henderson: "Demonstration of a Carbonator for Quantitative Carbon-dioxide Therapy." Read by title.

Paul Lewis: "Further Observations on the Relations of Vital Stains to the Tubercle."

T. S. Githens and S. J. Meltzer: "On the Course of the Toxic Effects of Ether and Chloroform under Intratracheal Insufflation."

T. S. Githens: "On the Influence of Decerebration upon Morphin Tetanus in Frogs."

I. S. Kleiner (by invitation): "On the Effect of Sodium Bicarbonate and Sodium Chloride upon the Convulsions produced by Heroin and Strychnin."

J. Auer and S. J. Meltzer: "The Influence of Pituitrin upon the Depressor Action of the Vagus Nerve in Cats."

B. T. Terry: "The Influence of Heat upon the Toxicity for Trypanosomes of Blood containing Transformed Atoxyl."

B. T. Terry: "Variations in the Toxicity of Transformed Atoxyl for Trypanosomes caused by Altering the Number of Organisms."

#### EXECUTIVE SESSIONS

The following officers were elected for the year 1913:

*President*—Torald Sollmann.

*Secretary*—John Auer.

*Treasurer*—A. S. Loevenhart.

*New Members of the Council*—J. J. Abel, Wm. de B. MacNider.

*Membership Committee*—C. W. Edmunds was reelected to serve three years, and the place made vacant by Dr. Sollmann's election to the presidency was filled by the election of Reid Hunt.

*New Members*—Among the candidates for membership investigated by the membership committee, the following were favorably reported to the council, recommended for election, and elected by the society: Henry Gray Barbour, Yale Medical School; Clyde Brooks, University of Pittsburgh; Cary Eggleston, Cornell Medical School; P. J. Hanzlik, Western Reserve Medical School; D. E. Jackson, Washington University; I. S. Kleiner, Rockefeller Institute; Oscar H. Plant, University of Pennsylvania; A. H. Ryan, University of Pittsburgh; Frank P. Underhill, Yale Medical School.

At the last business meeting the Pharmacological Society passed a vote of thanks to the Western Reserve University for the hospitality extended and to the local committee, Drs. Macleod, Sollmann and Pearce, for its thorough arrangement of all the details which made the Cleveland meeting so pleasant.

J. AUER,  
*Secretary*

#### THE TENNESSEE ACADEMY OF SCIENCE

THE second session of the first annual meeting of the Tennessee Academy of Science was held at Carnegie Library Hall, University of Tennessee, Knoxville, Tennessee, on November 29–30, 1912.

The following papers were given:

#### NOVEMBER 29: MORNING SESSION, 10 A.M.

"The Taste Sense in Frogs," Alice N. Porter.

"Hydrogen Peroxide as a Bleaching Agent for Entire Insects," E. C. Cotton.

"Relation of the State to its Water Power Resources," J. A. Switzer.

"The Recent Disturbance in the Northern Equatorial Belt of Jupiter" (read by Professor Porter), Latimer J. Wilson.

#### AFTERNOON SESSION, 2 P.M.

"The Effects of a Soy Bean Crop on a Following Cereal," Maurice Mulvania.

"The Fourth Dimension," Samuel M. Barton.

"The Occurrence of Aerial Roots on the Virginia Creeper," Samuel M. Bain.

"Micro-color Photography," Samuel M. Bain.

#### EVENING SESSION, 7:30 P.M.

Address by the retiring president, "Science and Progress in the South."

"The Mastodon and the Glacial Age" (illustrated), W. E. Myers.

Reception to visiting members by the faculty of the University of Tennessee.

#### NOVEMBER 30, 9:00 P.M.

"Defraction Phenomena Due to the Dimensions of the Source of Light," Brown Ayers.

"Studies in Feeding Habits of *Amæba*," Asa A. Schaeffer.

"The Slates of Georgia," T. Poole Maynard.

"The Importance of the Study of Meteorology in its relation to Agriculture," J. F. Voohees.

"The Breaking of the Nashville Reservoir, November 5, 1912" (illustrated), Wilbur A. Nelson.

"Types of Iron Ore Deposits in East Tennessee," C. H. Gordon.

The following officers were elected for the ensuing year:

*President*—Watson Selvage, University of the South, Sewanee.

*Vice-president*—G. A. Dyer, Vanderbilt University, Nashville.

*Secretary*—Wilbur A. Nelson, Tennessee Geological Survey, Nashville.

*Treasurer*—Samuel M. Barton, University of the South, Sewanee.

*Editor*—R. M. Ogden, University of Tennessee, Knoxville.

The following resolutions were passed on the conservation of Tennessee's water power and exhibits at the national expositions:

"WHEREAS, it is becoming increasingly evident that the water power of our state is becoming appropriated to corporate use and alienated, perhaps forever, from the control of the commonwealth, to the great detriment of this and future generations, we, the Tennessee Academy of Science, respectfully recommend to his excellency, the governor, and to the legislature of the state of Tennessee, the immediate passage of a law authorizing the governor to appoint a conservation commission which shall have power (1) to grant, under such restrictions as are hereinafter suggested, renewable franchises for a limited term, to all corporations desiring to make use of said water power; (2) to secure a permanent water supply, provide for the cooperation of the state in forestry conservation, and the eventual creation of a state forest reserve; (3) to prevent the diversion of the electric power derived from the natural waters of Tennessee to the enrichment of other states, and to encourage its utilization within our own borders, and to that end (4) to cooperate with the boards of trade and other civic bodies to secure the location of industrial plants in all localities where power is cheap and abundant, and (5) to assure a more permanent and lasting supply of cheap power throughout this state in all parts thereof, whether blessed with water power or not, by the prevention of waste in mining and use of coal.

"We further recommend that the commission be instructed to investigate the feasibility of a statewide system of power conservation, development and transmission, whereby every section of the state may enjoy an equitable share of the benefit thereof; and that the commission report its findings to the next session of the legislature.

"We suggest further the appointment on said commission of a practical expert in each of the following departments of activity: hydro-electric engineering, forestry, mining and scientific business management.

"To these ends we recommend the enactment of legislation similar to that already in force in the states of New York and California, providing for the conservation of their natural resources."

"In view of the three great expositions which are to be held in the near future, viz., the National Conservation Exposition, Knoxville, Tenn., 1913, the National Exposition, San Diego, Cal., 1914, and the Panama Canal Exposition, San Francisco, 1915, the Tennessee Academy of Science, at its annual convention in Knoxville assembled, urges that the present session of the legislature should take immediate action to provide for an exhibit that shall properly and adequately set forth the resources of the state, especially in her water powers, her agricultural opportunities, her forests, her mineral wealth and her manufacturing advantages.

"It is suggested that an exhibit that could be used successively in the different expositions above named would advertise the state widely, without a proportionate cost, and would prove to be of extreme material value to the state."

Members from all sections of the state were present at this, the first annual meeting of the academy.

WILBUR A. NELSON,  
*Secretary*

CAPITOL ANNEX,  
NASHVILLE, TENN.

#### THE NEW YORK ACADEMY OF SCIENCES

THE academy and its affiliated societies held their annual dinner, Monday evening, December 16, at the Hotel Endicott. After the dinner, the annual meeting of the academy was held, at the conclusion of which Mr. Emerson McMillin gave his address as retiring president, in which, after reviewing the present condition of the academy as derived from conference with a large number of the men who have long been active in carrying on its various lines of work, he made several recommendations regarding the plans which might be adopted for enlarging the usefulness and interest of the organization and its meetings. The address will be printed in full in the concluding portion of Vol. 22 of the *Annals*. At the close of President McMillin's address, Mr. V. Stefánsson gave a most interesting summary account of the expedition which he and Dr. R. M. Anderson made along the arctic coast of western North America, from Point Barrow to Coronation Gulf, during the years 1908-12 inclusive. At the close of his lecture, Mr. Stefánsson outlined the plans of the second expedition which he is now organizing for geographical and ethnological work on Victoria, Banks and Prince Patricks Islands in the years

1913-16 inclusive, and indicated the manner in which his expedition and the Crocker Land Expedition will supplement each other's work.

The report of the corresponding secretary showed that the academy had lost by death, during the past year, the following honorary members: Sir George H. Darwin, elected 1899; Sir Joseph D. Hooker, elected 1907; M. Jules Poincaré, elected 1900; Geh. Rath Professor Ferdinand Zirkel, elected 1904.

At the meeting five honorary members were elected, namely: Professor Frank D. Adams, geologist, McGill University; Dr. George E. Hale, astronomer, Mt. Wilson, California; Professor Iliya Metchnikoff, biologist and bacteriologist, Pasteur Institute, Paris; Sir John Murray, geographer and oceanographer, Edinburgh; Professor Sho Wataſe, zoologist, Imperial University of Tokyo.

According to the report of the recording secretary, the academy held 8 business meetings and 26 sectional meetings during the year ending November 20, 1912, at which 65 stated papers were presented. Four public lectures were given at the American Museum of Natural History, to the members of the academy and its affiliated societies and their friends. The academy now has on its rolls 468 active members, including 22 associate members, 86 fellows, 90 life members and 11 patrons. There are in addition to this number, 20 non-resident members on the rolls. Announcement was made with regret of the loss by death of the following members: Messrs. John Jacob Astor, George Borup, Charles F. Cox, Morris Loeb, William Pennington, Edward Russ, John B. Smith, Isidor Strauss, James Terry and John Weir.

The treasurer's report showed receipts of \$7,648.17 and expenditures of \$6,992.66 during the fiscal year, including an investment of \$975, leaving a cash balance on hand November 30 of \$1,555.51.

The librarian reported that the library of the academy had received, through exchange and donation, 313 volumes and 1,670 numbers. Much of the effort made to complete imperfect files has been successful. The library has been open for the consultation of books every week-day from 9:30 A.M. to 5 P.M., and the use of the academy's books has increased noticeably.

The editor's report stated that pages 177-263 of Vol. XX. and pages 1-160 of Vol. XXI. had been distributed, and that pages 161-337 of the latter volume were now ready for distribution.

The annual election resulted in the choice of the following officers for the year 1913:

*President*—Emerson McMillin.

*Vice-presidents*—J. Edmund Woodman, W. D. Matthew, Charles Lane Poor, W. P. Montague.

*Corresponding Secretary*—Henry E. Crampton.

*Recording Secretary*—Edmund Otis Hovey.

*Treasurer*—Henry L. Doherty.

*Librarian*—Ralph W. Tower.

*Editor*—Edmund Otis Hovey.

*Councillors* (to serve 2 years)—Frederic A. Lucas and R. S. Woodworth.

*Members of the Finance Committee*—Emerson McMillin, Frederic S. Lee and George F. Kunz.

E. O. HOVEY,

*Recording Secretary*

## SOCIETIES AND ACADEMIES

### THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE thirteenth regular meeting of the society was held at the residence of Dr. Pfender, January 7, 1913, Dr. Pfender acting as host and Dr. Stiles as chairman.

The following were elected as corresponding members: American—C. C. Bass, Samuel T. Darling, W. B. Herms, George R. LaRue, Theobald Smith and Richard P. Strong; foreign—E. Brumpt, J. B. Cleland, Bruno Galli-Valerio, L. Gedoelst, B. Grassi, A. Henry, J. Ch. Huber, C. Janicki, T. H. Johnston, E. Loennberg, A. Mrázek, Wm. Nicoll, S. von Ratz and K. Wollfluegel.

Mr. Hall presented the following note:

*A Spurious Parasite Reported as Trichinella.*

In 1905 and 1908 Staeubli published his method of examining blood for blood parasites. The method consists in adding 3 per cent. acetic acid to fresh blood in order to dissolve the erythrocytes and centrifuging to bring down the blood parasites. In his paper in 1908 he states that it will probably be possible to diagnose trichinosis in suspected human cases by examining blood from a finger or ear puncture instead of resorting to muscle excision.

Since then 3 cases of the finding of *Trichinella* by the use of Staeubli's method in human cases have been reported in the *Archives of Internal Medicine*. Herrick and Janeway (1909) reported a case from New York City in which *Trichinella* was recovered on two occasions in blood from the arm veins. Their specimens were passed on by Drs. Flexner and Oertel also, and judging from this and the photomicrograph they give, their findings should be accepted. Mercur and Barach

(1910) reported a second case from Pittsburgh. They state that the embryos correspond exactly to the one shown in Herriek and Janeway's illustration and their photomicrograph of a parasite from a gastrocnemius excision in the same patient is certainly one of *Trichinella*. Cross (1910) reported a third case from Minneapolis, in which the embryos are said to have been found in one cubic centimeter of blood from ear puncture. He gives a photomicrograph of one and states that two others "were not quite so clearly marked."

An examination of Cross's photomicrograph shows a straight body of homogeneous structure and quite devoid of internal granular or cellular bodies. Along the sides are two dark lines indicative of a high light refraction. This is probably a plant hair or some such object. The trash also shown in the photo indicates that Cross was not successful in guarding against contamination, as advised by Staebli, and the presence of plant hairs or similar objects under such conditions is what would be expected. The ratio of the length to the width of the object, which ought not to be greater than 26:1 for a *Trichinella* embryo in the blood, is about 36:1. These facts, taken in connection with Cross's statement that he found two other specimens which were not quite so clearly marked, indicate that Cross was dealing with plant hairs or some similar foreign bodies simulating *Trichinella*, and the case should not be retained as a case of *Trichinella* discovered in the circulating blood. The only clinical symptoms given—facial edema and a 44 per cent. eosinophilia—leave the case open as far as the existence of a trichinosis is concerned.

Dr. Ransom presented the following note:

*The Origin of some High Percentages of Cysticercosis in Cattle.*

In a note read before this society and published in SCIENCE for April 19, 1912, the writer called attention to some cases of infestation of cattle with *Cysticercus bovis* in which three lots of 251, 70 and 201 head had 25, 41 and 39 head, respectively, infested. These cattle were all from the same locality and an examination of the surroundings showed the following conditions, according to the report of Dr. Eagle, of the U. S. Bureau of Animal Industry: (1) the intake of the water supply for the cattle troughs was in a small river 75 yards below the outlet of the sewer from the city where the cattle were being fed; (2) in the cattle yard was a stagnant pool which was the only water the cattle had to drink when the

regular supply was frozen, as it frequently was during the winter, and this pool received the drainage from an area containing the privies of the establishment where the feeding was done and from part of the city where soil pollution existed; (3) the cattle were fed cotton seed hulls which were more or less contaminated with human feces, as it was a common practise of the employees of the establishment to defecate in the buildings where the hulls were stored. Such surroundings give almost perfect conditions for infestation with *Cysticercus bovis*.

Dr. Stiles presented the following notes on technique and treatment:

In centrifuging feces in fecal examinations, the State Board of Health of Kentucky, instead of using a centrifuge tube, is now using ordinary glass tubing, smoothed off at the ends after cutting to the length of the centrifuge tube. These tubes are corked at both ends. After centrifuging in the tube holder, the upper fluid is poured off and the sediment is taken out at the bottom by the removal of the cork, the cork being used in smearing the feces on the slide. Dr. Stiles has found this a very satisfactory proceeding, but states that on several occasions he has found eggs by the ordinary smear method in cases which were negative by the centrifuge method.

Judging from several cases in which it has been tried, the use of flowers of sulphur seems to be of promise in the treatment of infections with *Strongyloides stercoralis*. It also appears to be successful in the one case of flagellate diarrhea in which it has been used. This was a case with an excessive infestation, the stools being almost pure cultures of the flagellate. In hookworm infection flowers of sulphur has not been found of use. For hookworm the routine treatment which has been found most satisfactory consists in administering the thymol in three doses, instead of two, at 6:00, 7:00 and 8:00 A.M., followed by coffee at 9:00, Epsom salts at 10:00 and coffee and crackers at 10:30.

In addition to the humanitarian and medical points of view in the prosecution of the hookworm campaign, Dr. Stiles noted that the enormous waste of time, effort and expense in pregnancies that are to lead to children of inhibited development who will die before maturity as a result of hookworm disease, is a point that has made a considerable impression upon southern women.

MAURICE C. HALL,  
Secretary

NEW SERIES  
VOL. XXXVII. No. 945

FRIDAY, FEBRUARY 7, 1913

SINGLE COPIES, 15 CTS.  
ANNUAL SUBSCRIPTION, \$5.00

## Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. Not only does this work give the salient facts of structural zoology and the development of the various branches of animals, but also the natural history—the *life and habits*—thus showing the interrelations of structure, habit and environment.

By L. S. Daugherty, M.S., Ph.D., Professor of Zoology, State Normal School, Kirksville, Mo.; and M. C. Daugherty, author with Jackson of "Agriculture Through the Laboratory and School Garden." Part I—*Field and Laboratory Guide*—12mo of 275 pages, interleaved. Cloth, \$1.25 net. Part II—*Principles*—12mo of 406 pages, illustrated. Cloth, \$2.00 net.

## Drew's Invertebrate Zoology

Professor Drew's work gives the student a working knowledge of comparative anatomy and leads him to an appreciation of the adaptation of the animals to their environments. The type method of study is followed.

PROF. JOHN M. TYLER, Amherst College: "It covers the ground well, is clear and very compact. The table of definitions is excellent."

*Invertebrate Zoology*. By Gilman A. Drew, Ph.D., Professor of Biology, University of Maine. 12mo of 201 pages. Cloth, \$1.25 net.

## McFarland's Biology

This work has chapters on the origin of life and its manifestations, the cell and cell division, reproduction, ontogenesis, conformity to type, divergence, structural and blood relationship, parasitism, mutilation and regeneration, senescence, etc.

PROF. W. R. McCONNELL, Pennsylvania State College: "It has some admirable features, the most valuable of which is the careful résumé of the subjects of heredity and evolution."

*Biology: General and Medical*. By Joseph McFarland, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia. 12mo of 440 pages, illustrated. Cloth, \$1.75 net.

## Stiles' Nutritional Physiology

Dr. Stiles takes up each organ, each secretion concerned with the process of digestion, discussing the part each plays in the physiology of nutrition—in the transformation of energy. A valuable feature is Dr. Stiles' happy use of homely similes to illustrate the more obscure physiologic actions.

PROF. COLIN C. STEWART, Dartmouth College: "It is remarkable for the fineness of its diction and for its clear presentation of the subject."

*Nutritional Physiology*. By Percy G. Stiles, Assistant Professor of Physiology in Simmons College; Boston. 12mo of 271 pages, illustrated. Cloth, \$1.25 net.

W. B. SAUNDERS COMPANY

West Washington Square, Phila.

# Longmans' New Books

## *The Principles of Applied Electrochemistry*

By A. J. ALLMAND, D.Sc., Fellow of the Chemical Society, Member of the Faraday Society, Member of the Bunsen Gesellschaft. With 136 Illustrations. 8vo. Pp. xii+547. \$5.00 net (Postage 23 cents).

## *Textile Design and Color : Elementary Weaves and Figured Fabrics.*

By WILLIAM WATSON, Superintendent and Lecturer in Textile Manufacture, the Royal Technical College, Glasgow ; formerly Headmaster of the Textile Departments of the Royal Technical Institute, Salford, and the Technical School, Shipley. With 413 Diagrams. 8vo. Pp. xii+360. \$2.50 net (Postage 18 cents).

## *Practical Measurements in Radio-Activity*

By W. MAKOWER, M.A., D.Sc., Lecturer and Demonstrator in Physics in the University of Manchester ; and H. GEIGER, Ph.D., Lecturer in Physics in the University of Manchester. With 61 Diagrams. Crown 8vo. \$1.60 net (Postage 10 cents).

## *An Introduction to Mathematical Physics*

By R. A. HOUSTOUN, M.A., Ph.D., D.Sc., Lecturer on Physical Optics and Assistant to the Professor of Natural Philosophy in the University of Glasgow. 8vo. Pp. x+199. \$2.00 net (Postage 13 cents).

## *Experimental Physiology*

By E. A. SCHAFER, F.R.S., Professor of Physiology in the University of Edinburgh. With 83 Illustrations. 8vo. Pp. viii+111. \$1.35 net (Postage 8 cents).

## THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

### SECTION F—IS IT WORTH WHILE?

THE first meeting of the American Association for the Advancement of Science was held in September, 1848. The society was not then organized into sections, but a committee on organization was empowered to "divide up sections" or "combine sections" as it deemed advisable.

The *Proceedings* of the Association indicate that for many years this committee was at least an active one, for the particular organization into sections and subsections of any one meeting rarely survived for another meeting.

At the sixth meeting, held in August, 1851, the following sections were recognized: A—Mathematics and Physics, B—Chemistry and Mineralogy, C—Geology and Physical Geography, D—Natural History, including Physiology, E—Ethnology and Geography, and F—Mechanical Science.

At the seventh meeting held in July, 1853, botany and zoology were recognized as subsections of Section B, which had been changed from "Natural History including Physiology" to "Chemistry and Natural History." The next year zoology was conspicuous by its absence, but two zoological papers were read in the subdivision designated "Physiology." The year following "Physiology" was omitted and "Zoology" was reinstated. Thus zoology, now prominent and now not in evidence, drifted in

<sup>1</sup> Address of the vice-president and chairman of Section F—Zoology—American Association for the Advancement of Science, Cleveland, December, 1912.

and out down to the thirty-first meeting held at Montreal in August, 1882. At this meeting "Biology," including botany and zoology, was designated as Section F and "Histology and Microscopy" as Section G.

For ten years the twins—botany and zoology—constituted Section F. At the forty-second meeting held at Madison, Wisconsin, in August, 1893, the twins parted company, zoology becoming Section F and botany, Section G. The Vice-president of Section F was Henry F. Osborn, who delivered the first vice-presidential address before the section. The secretary of the section was L. O. Howard.

But few vice-presidents have failed to follow the example of Vice-president Osborn. Two years ago sickness prevented the vice-president attending the meeting held at Minneapolis, but his address was read by another member of the section. Last year the vice-presidential address was omitted from the program because Vice-president Reighard and the other officers were convinced that but few zoologists would attend the Washington meeting. Their judgment was vindicated in so far as the number in attendance can be considered a vindication.

On the whole, the record of Section F as preserved in the *Proceedings* of the Association is very creditable and can hardly be called discouraging. Moreover, the list of zoologists who have taken an active part in the meetings of the association includes the names of most of our eminent and honored zoologists.

Why then ask you to consider whether it is worth our time and energy to maintain Section F as an active, vital unit in the Association?

Well, Section F can be thought of as an organism—at least it is an organization composed of living animal units—and I dare say it is no reflection upon you to as-

sume that as zoologists we are all interested in living things and their functions and all the conditions that affect their vitality and effectiveness. But let me put you at ease, so far as I can, by assuring you that I am not going to tire you with an effort to work out this figure in detail.

The immediate suggestion and justification for my apparent disregard of the traditional character of vice-presidential addresses lie in the unrecorded facts pertinent to the life of Section F and in the attitude of indifference to and even open repudiation of the section assumed by some zoologists in recent years. It may be that the phenomena interpreted as evidences of destructive metabolism are merely expressions of efforts at readjustment. If so, I hope I shall be considered among those who desire a proper readjustment. If, on the other hand, the phenomena are indications of a real tendency toward disintegration, I trust I may have some part in at least checking that tendency long enough to enable us to come to a full realization of what disintegration of the section would mean for zoology in general.

Bear with me, then, while I bring to you some of the facts and observations which have a bearing upon the position of Section F as I see it.

Section F, as already stated, was organized in 1893. The objects of the section, as expressed in the constitution of the Association, are:

by periodical and migratory meetings, to promote intercourse between those who are cultivating science in different parts of America, to give a stronger and more general impulse and more systematic direction to scientific research, and to procure for the labors of scientific men increased facilities and a wider usefulness.

The American Society of Naturalists was organized in 1883 with the object of associating

working naturalists for the discussion of methods of instruction, museum administration, and other objects of general interest to investigators and teachers of natural science; and for the adoption of such measures as shall tend to the advancement and diffusion of the knowledge of natural science.

The list of meeting places of this society clearly indicates that the society practically has been an eastern organization. The addresses and discussions, in so far as one can judge by their titles, indicate that some of the objects announced in section 2 of the constitution either have been overlooked or are not what the language of the section suggests.

In 1899 a call was issued to the naturalists of the central and western states to meet at Chicago for the purpose of considering the organization of a western branch of the American Society of Naturalists. This meeting was so encouraging that another meeting was held at the University of Chicago in 1900. The second gathering was even more successful than the first. Indeed it was so large that, in the language of the minutes, it "became necessary to hold two sections, a zoological and a botanical."

The segregation thus forced upon the botanists and zoologists in 1900 was again observed in 1901, when the Eastern Branch and the Central Branch of the American Society of Naturalists and the American Morphological Society met at the University of Chicago. At this meeting the zoologists appointed a committee on organization and during Convocation Week of 1902-03 organized the American Society of Zoologists, consisting of an Eastern Branch and a Central Branch. The constitution of this society declares the objects to be

the association of workers in the field of zoology for the presentation and discussion of new or important facts and problems in that department of science and for the adoption of such measures

as shall tend to the advancement of investigation in that science in this country.

The scope of the society is further indicated by the restriction of membership to "active workers in the field of zoology and who have contributed to the advancement of the science."

The American Morphological Society was organized in 1890 in recognition of "a very noticeable increase in the number of persons in this country who are devoting themselves to the study of animal morphology," and also with a desire to break up the "scientific isolation" resulting from "the vast extent of territory over which our students are scattered." From the beginning this society was distinctively eastern, notwithstanding the fact that it recognized the vastness of our territory and expressed a desire to break up "scientific isolation."

In addition to the above there have been organized since the establishment of Section F, the American Association of Anatomists, the American Society of Biological Chemists, two societies of entomologists, the American Nature-study Society, the American Physiological Society, the American Psychological Association, the American Association of Museums and the American Breeders Association with a special section on eugenics. Each of these organizations has come into existence in response to a demand and each has some specific and circumscribed end or ends in view. All have drawn from the group of workers that but about twenty years ago constituted Section F. Membership in some of them naturally means separation from Section F, while membership in others ought to just as naturally mean active membership in Section F. For even when, as I have intimated, the declared objects of these organizations suggest a field of usefulness outside of the circle of the select

few the records do not suggest any activity beyond the circle. This is quite natural and under our conditions is inevitable.

I trust you will not misinterpret my brief comments on the declared objects of these societies. I am not criticizing, but am trying to present as briefly as possible some of the important facts and conditions that have a bearing upon my question.

Apparently there is still a demand for these organizations. All of them emphasize the fact that specialization and segregating grouping has become necessary. I dare say none of us will deny that the segregation of specialists is a natural process and that we shall always have the groups now organized, or others to be established as our points of view and interest shift. You may regret it and to some extent even rebel against it, but you can not ignore it and have a part in the progress of science. In yielding to this pressure, however, we may go to such an extreme as to fall far short of legitimate expectations. And I am constrained to declare that the tendency of eminent zoologists to ignore Section F and even to speak slightly of it indicates a sad misconception of our relations to society at large.

Only the declaration of the American Society of Naturalists to adopt such measures as shall tend to the advancement and diffusion of the knowledge of natural science indicates a recognition of our obligations to all our fellow-citizens that is somewhat differently suggested in the "increased facilities and a wider usefulness . . . for the labors of scientific men" of the American Association for the Advancement of Science.

Neither the Society of Naturalists nor Section F has lived up to the program of general usefulness. The addresses, and quite naturally the papers, have been prepared with reference to the zoologists

within the circle rather than with reference to those who are not specialists and in whom we should foster and develop an interest in the science for the general good.

In this, I think, lies the suggestion of the point where we shall discover our weakness and the hope for a wider influence and usefulness.

The Society of Naturalists can not be justified unless it really is what the name intimates, and under the present system of organizations and affiliations its meetings can not truly be meetings of naturalists unless the botanists, zoologists and other naturalists meet at the same place and time. The botanists have kept in close touch with Section G of the Association, but the zoologists have recently tended toward independence and separation from Section F by making the meeting places of the association a minor factor in the selection of the meeting places of their societies.

Are there any reasons why zoologists should emulate the example of the botanists and show a keener interest in the possibilities of Section F? I think there are, and I shall try to present one that has been uppermost in my thoughts recently.

I shall not enumerate the social and personal advantages of meeting at the same time and place set for numerous other scientific societies and sections of the association. These advantages have been fully presented and without doubt are admitted by all of us. At present there is uppermost in my mind just one point of view, namely, Section F as the zoologists' natural avenue to the general public.

As a foundation for my plea for a wider usefulness of Section F, I postulate the following two propositions:

1. No scientific organization in this country receives such general attention and, for a time at least, creates so widespread an interest in human knowledge

and achievement as does the American Association for the Advancement of Science.

2. Every department of science that appears as a part of the association at its meetings shares this touch with the general public in proportion to its activity and the interest it expresses in the public at large.

In my judgment these propositions are statements of facts and not inferences. Accordingly, I leave them without attempting to support them by argument, and ask: Can we as zoologists afford to ignore—nay, are we doing our full duty when we give little or no thought to our possible influence outside of the circle of our laboratories?

When I see men and women rushing from city to city or racing across the continent in automobiles in search of health or invigorating “rest,” I soften my judgment with the fond hope that some day the zoologists and botanists of our universities, colleges and normal schools will send out teachers prepared to plant in the heart of every school boy and girl a love for nature that will become a heritage to be handed down from generation to generation as an invaluable asset for the health and happiness of the race.

Of course, the realization of this hope will not come until it is much more generally appreciated that, nature not being man-made, communion with her in “God’s out-of-doors” compels man to leave the worn paths of human activity and diverts his attention to the things that are ever attractive and vitalizing. There are relatively few of us who are teachers, and still fewer of those who are preeminently investigators, giving due weight to this point of view. As a rule zoologists are either ignorant or indifferent to the opportunity open to them for service in this direction, and in consequence are failing to fully discharge their sacred obligations to society.

Everywhere I find among thinking men and women a strong undertone of an unexpressed, an uncrystallized sentiment that for some reason or other zoology is not meeting a demand that ought to—that must exist in the best civilization. And whenever I have outlined a plan of what might be called natural history courses designed especially for teachers and prospective teachers, I have been most enthusiastically urged to carry out the plan and provide something similar for the students who are not selecting zoology or botany as the major line of work.

The love of living things as individuals in a community is inseparable from the social or gregarious instinct. And when we have reached years of discretion and instinctively seize essentials, letting go the non-essentials, we are still children at heart. The child humanizes the actions of the animals that come into its experience and names them as spontaneously as it does the cousins, uncles and aunts. And no matter how absorbed we may become in chromosomes, we are content and happy only when we call the animals we see and hear by name. The intellect may find satisfaction in the contemplation of the obscure and the abstract but the man of heart must have the concrete individual.

I venture to assert that every successful teacher of zoology who awakens an active interest in animal life and who fosters a love for nature is successful by virtue of his personal experience with animals in their native environment. A class tired and weary of the scientific discussion of a morphological or embryological question can be put on the *qui vive* any time with a story personal to some particular animal or group of animals. Time and time again I have seen students weary unto sleepiness awakened and kept awake for an hour by an account of a simple but personal ex-

perience with some animal. What teacher has not been struck by the tenacity and even accuracy with which students hold the accounts of personal experiences and the lessons drawn from them when their minds were like quicksand for morphological data!

But let us be honest with ourselves and remind ourselves that most of our students go out to give in miniature or in more or less condensed form what we give them in our laboratories and lecture rooms. The kind of zoology to which the great majority of the coming generation is to be introduced will be largely, if not altogether, determined in our universities and colleges by the men and women who constitute the membership of Section F and affiliated societies.

It should also be remembered that the wider the circle of those interested in a science the greater will be the appreciation of the work and efforts of the investigators in that field and the greater will be the possibilities in every direction. To take thought of service to the general public through our general courses in zoology from the schools to the colleges and universities and through such natural avenues to the public as Section F, is to indirectly but certainly increase the appreciation and support of all lines of zoological investigation and to give the investigator, as well as the teacher, in the field of zoology a more honored and generously supported position. Consequently, in view of the unique position I have assigned to Section F it is natural for me to bespeak a warmer interest in the section and a sympathetic cooperation for the officers.

Before concluding my brief plea permit me to protect myself against a possible misunderstanding. My plea is for Section F and the recognition of a need which I feel most of us do not recognize in service. In

the presentation of this need and opportunity I am not decrying our present type of university course in general zoology. Neither do I advocate nor believe in replacing the usual university course in general zoology by a so-called old-fashioned natural history course or what some of the younger protestors are pleased to call ecology. No, I believe in what we may call the morphological course illuminated with a common-sense presentation of the machine in action and in its becoming. A critical examination of conditions I think will disclose as a fact that the protesting zoologists are misplacing their criticisms. The general dissatisfaction we hear about (which probably is not as general as some think it is) is not so much a result of the character of the courses offered as it is of the quality of our students. The courses, as a rule, are fit and proper and not a bit too exacting for a student of university caliber. But many of our students are not of university caliber in reference to zoology. That is the weak link in the chain. Our students should come from the high schools, preparatory schools and minor colleges with a better knowledge of animals as living individuals and with more knowledge of the physical sciences. But many of them come without any of this knowledge or with the background of a nature-study course often worse than nothing.

To crowd out of the university the exacting morphological course with a gossipy informational course of the hunter and fisherman and superficial poet is to replace sound learning and the development of mental fiber and capacity with sentimentality and undifferentiated—aye, undifferentiable protoplasm in the brain. We must not lower our standards and ideals to those of the vaudeville nor those of the moving picture shows nor those of the newspapers and current novels, but we must insist

upon keeping them up and do our best to make possible the proper preparation of the students.

With teachers prepared to teach zoology as probably we all feel it should be taught in our schools, and consequently with our students quite ready for a deeper look into animal life, and with a more widely distributed interest in zoological work, we shall find the more or less vague feeling for something that is wanting vanished and shall have a larger and more capable class of applicants for more special and advanced courses. Until this condition is realized we must as best we can provide for both classes of our students as well as for the preparation of the men and women who are to bring the rich blessing of a general interest in natural history to the commonwealth.

In the progress toward the realization of this worthy end Section F, in my humble judgment, can be made a most efficient factor by serving as the one sure and safe link between the general public and the zoologists as investigators and teachers.

The preparation being well done below the plane of the investigator, or, if you prefer, outside the circle of investigators, Section F will continue as a vigorous branch of a fruitful vine, and, being trained to meet the conditions of its general environment will yield to the people at large attractive, choice and satisfying fruit.

H. F. NACHTRIEB

---

THE UNITED STATES GEOLOGICAL  
SURVEY<sup>1</sup>

THE record of the work of the Geological Survey during the fiscal year 1912 may fitly be preceded by a statement of the conditions under which that work has been done, not as an apology for either the

quantity or quality of the results of the investigations made, but rather as an exhibit of the limitations forced upon this bureau—limitations on economy and efficiency which seriously hamper all efforts for better administration in the expenditure of public money.

The offices of the Geological Survey have become wholly inadequate and unadapted to its needs. Since 1884, when the Survey was first quartered in the Hooe Building, at 1330 F Street, the effort has been frequently made to provide for the growth of the organization by adding wings and extensions to the building, but every increase in floor space has been made at the expense of proper lighting of the older portions of the building, so that its fitness for the Survey's use has been steadily impaired, and the resultant conditions constitute an actual detriment to health and a menace to life and property, as well as an obstacle to efficiency. The conditions under which the Survey employees work in the Washington office are to be condemned for both humanitarian and business reasons. . . .

The present housing of this federal bureau is unworthy of the nation. Both the work and the workers of the United States Geological Survey have an international reputation, and visiting foreign scientists do not conceal their astonishment at the miserable environment in which these investigations are being carried on. Our neighbors on this continent, in Canada and Mexico, have erected buildings especially adapted to the work of their geological surveys, which are properly housed, as is nearly every other geological survey in the world, and yet the geological survey of no other nation compares in size of organization or scope of work with that of the United States. In fact, the surveys of several of the larger European countries are organizations whose personnel is com-

<sup>1</sup>Extracts from the Thirty-third Annual Report of the Director.

parable in number only with that of single divisions of the American Survey.

The practical side of this feature is the increased inducement that suitable quarters would afford in retaining in the government service men of the highest professional talent. At best, most of these investigators are carrying on their government work at a financial sacrifice, and the temptation to go into professional or corporation work at largely increased salaries is strengthened by the contrast between the well-lighted and sanitary offices generally provided in the business world and the noisy, dirty, dark and crowded quarters offered by the Survey. To retain in the government service the best men is by far the largest administrative problem of the director of the United States Geological Survey.

Notwithstanding the growth of the Survey work along practical economic lines, scientific work has not been neglected. In fact, in the Geological Survey the scientific investigations are inseparable from the economic work, though the one or the other may predominate in purpose according to the needs of the particular research in hand. In any field economic work of the highest rank is impossible without full knowledge of the scientific laws and principles pertaining to the subject of the work; but as there is no application of geology which does not involve unsolved problems, some of them of the highest importance, the best knowledge available is nevertheless relative. It thus follows that the broad and searching observations which should accompany every piece of good economic work comprehend data that are eventually combined in the construction of new scientific hypotheses, some of which, as more observations accumulate, grow into established laws or principles that are in turn of the greatest practical consequence. Thus

the detailed studies of the metalliferous deposits in one region or another bring to light evidence from which to determine the genesis of the ores and the modes or conditions of their occurrence, and the economic inquiry becomes more intelligent and successful when once this new principle regarding the mode of an ore occurrence is understood.

On account of the plain duty of this federal service to minister to the immediate needs of the various mining districts, it is not generally possible to concentrate and direct the observations to a series of regions systematically chosen as suited soonest to furnish the requisite data bearing especially on some particular scientific problem, however important and advantageous its solution may be; but nevertheless the data are gradually accumulated for the interpretation of many of these problems without sacrifice of the Survey's obligations to the public. An interesting illustration of the deduction of a principle from data so accumulated is found in the paper by W. H. Emmons on the enrichment of sulphide ores, the manuscript of which has been completed during this year. Another illustration of scientific results based on a long period of field studies, pertaining mainly to economic areas, is found in the pre-Paleozoic history of central North America, as described in the monograph by Van Hise and Leith on the geology of the Lake Superior region, which appeared during the year.

Among other long-term studies more distinctly scientific in character may be mentioned particularly the investigations, made under Mr. Vaughan's direction, of the formations of the southern Coastal Plain and Gulf embayment, which, though having an economic object, are yielding important contributions to our knowledge of the stratigraphy, physiography and

geologic history of this province; the work under the direction of Mr. Cross in the San Juan region of southwestern Colorado, which, in connection with the thorough geologic studies made during the preparation of folios, is affording new scientific results of a higher order concerning especially the volcanism and physiography of the region; and the studies begun last year by Messrs. Campbell and Alden in the Glacier National Park, which promise important results concerning the origin of the structure and physiography of this part of the Rocky Mountains and of the glacial topography, which, as it is still "in the making," offers exceptional opportunities for scientific study as well as observation by the traveler interested in the natural wonders of his own country. Important regional studies of high scientific rank which should also be mentioned are those prosecuted by Mr. Keith and his associates, on the difficult stratigraphy and intricate geologic structure of the older Paleozoic regions of western New England and the Appalachian region, the results of which are partly published in folio texts, and those carried on by Professor Emerson in southern New England. A report by Professor Emerson on the geology of Massachusetts and Rhode Island has been submitted during the year.

The paleontologic work of the Survey continues to be of the highest rank. Many of its publications, written by the most distinguished representatives of the various branches of paleontology in the country and embodying experience and observations gathered during years of patient research, have contributed much to the scientific reputation of the organization. The descriptive paleontologic papers are often treated as "pure science," yet instructive, striking or tedious, as may be these delineations of the groups of animal or plant life which lived on the globe in some particular

epoch, there is not one of these papers describing the fauna or flora of a formation that does not prove sooner or later to possess practical value and to be essential to geology in its constantly increasing refinement of study and results. Without paleontology the geologic classification of formations, their correlation, and the determination of their mutual relations would be impossible. In fact, real and symmetrical progress in geology is impossible without corresponding interrelated development and refinement of its handmaid paleontology. The economic geology of any region of complicated structure is blind and inconsequent unless the time relations of the strata concerned are known. The monograph now being issued from the press on the Cambrian Brachiopoda, prepared by ex-Director Walcott and representing many years of painstaking study and distinguished attainment, embraces our best and most complete presentation of the criteria for the discrimination of the Cambrian formations in America and will for many years be a manual for the use of workers in Cambrian geology and paleontology. This monograph brings deserved credit to American science and to the Geological Survey, under whose auspices most of the work was accomplished. Other paleontologic publications specially deserving mention by reason of their scientific merit are J. P. Smith's philosophic treatment of the Middle Triassic faunas, and the monograph on the Mesozoic and Cenozoic Echinodermata of the United States by W. B. Clark and M. W. Twitchell, the manuscripts for both of which are now in hand. Work like that of Kindle on the Onondaga fauna, lately printed, and that by Berry on the Upper Cretaceous and Eocene floras of South Carolina and Georgia and by Stephenson on the Cretaceous deposits of the eastern Gulf region,

both now in manuscript, is indispensable to geology. In these papers the stratigraphic value and the practical application of the results of the paleontologic investigations are given much prominence. The two papers last named are based on materials gathered in the course of the study of the Coastal Plain already mentioned, the economic motive for which was the investigation of the underground water resources. They are therefore representative of a series of scientific reports resulting from studies whose immediate object is economic.

The folios describing and mapping in detail the geology of quadrangles in different parts of the country are regarded as mainly scientific, though always giving attention to the economic resources of the region. The areal studies now in progress in the valley region of central Alabama, a part of which has been described by Mr. Butts in the Bessemer-Vandiver and Montevallo-Columbiana folios, now in hand, promise important additions to the geologic history of the southern Appalachian region. On the other hand, the Claysville (Pennsylvania) folio, which has been issued during the year, affords a striking example of the first-hand aid in oil and gas development to be derived from the careful delineation of geologic structure and its economic explanation. Not inferior in scientific value to the papers just cited, though primarily economic, are such reports as those by Messrs. Brooks and Prindle on the Mount McKinley region, Alaska, and by Messrs. Calkins and Emmons on the geology and ore deposits of the Philipsburg quadrangle, in Montana.

An important and interesting effect upon the scientific work of the Survey has resulted from the work in land classification. The constantly increasing demand for both completeness and exactness of information regarding the mineral resources of the pub-

lic lands under classification have developed methods and scope of view in this economic work that have exerted a marked influence on the folio work in other areas.

Thus, the training and methods developed in the course of the classification of the coal lands have brought about higher standards of refinement in stratigraphy, as well as in economic work, in other regions of the country. Another very notable illustration of scientific results springing from the study of economic problems is found in the administration of the Weeks Act. The intensive hydrometric experimental studies carried on in order actually to show, in accordance with the terms of the law, the degree of protection afforded by forests to soil and water in certain areas proposed for purchase as national forests have resulted in empirical determinations and demonstrations of high scientific value as well as of tangible economic importance.

The principles governing the origin and mode of occurrence of petroleum and natural gas are as yet but fragmentarily grasped. Every oil field examined in detail contributes its data for use in the eventual interpretation of the problems, and each pool is studied with keen alertness for the discovery of some key which may aid in the coordination of the data, which sometimes, according to the region and conditions, seem, on account of our lack of knowledge, even to be in conflict. The observations made by the survey geologists in the oil and gas fields of California and Kentucky promise to further the solution of some of the problems, and by pointing out the relations of oil and gas occurrence to the geologic structure of the regions examined they have rendered important scientific as well as economic aid in oil and gas development; but the basic

principles controlling the widely varied modes of occurrence and accounting for the differences in kinds of the oils in widely separated regions are possibly still far from view.

On account of the more conservative and dignified character of the official publications of the Survey and the care taken to confine their substance to matters of demonstrated fact, they do not offer to the geologist the forum for free discussion of scientific theories and problems that are afforded by those periodicals and serial publications of scientific societies which are especially devoted to matters of strictly professional interest and which are more widely distributed among scientists. For this reason many of the scientific results of the Survey's operations are first published in these journals. Examples of papers of high rank contributed in this way are numerous. Without implying relative merit among these, mention as typical may be made of the paper by Mr. Campbell, "Historical Review of Theories Advanced by American Geologists to Account for the Origin and Accumulation of Soil," published in *Economic Geology*, Vol. 6, No. 4, and that by Mr. Ulrich, entitled "Revision of the Paleozoic Systems," printed in the *Bulletin of the Geological Society of America*, Vol. 22, No. 3. Besides contributing to the programs of other scientific societies in Washington, the members of the Survey maintain for the discussion of purely geologic topics three professional societies, including the Geological Society of Washington, before which Mr. Campbell's paper, just cited, was presented as a presidential address. Meetings of some one of these societies or of their sections average two a week for the winter and by far the greater number of the papers read are offered by members of the Survey.

#### EDUCATIONAL WORK OF THE SURVEY

Closely connected with the scientific work of the Survey is its educational function, which has not, on the whole, received the attention that so importantly useful a work deserves. The Survey has, however, in cooperation with several state surveys, participated in the preparation of a number of educational bulletins that have, in accordance with the agreements, been submitted to the respective states for publication. As distinctly educational in their scope, though far from elementary, should be named the valuable paper by Mr. Willis, entitled "Index to the Stratigraphy of North America," published as a professional paper in explanation of the new geologic map of the continent, and the paper by Messrs. Tarr and Martin, describing the earthquake phenomena in the region of Yakutat Bay, Alaska.

A notable contribution to the study of physiography was the Survey's Professional Paper 60, "The Interpretation of Topographic Maps," by R. D. Salisbury and W. W. Atwood, consisting chiefly of reprints of parts of the Survey's maps and of brief suggestions as to the origin and history of the features shown on them. For many years the topographic maps made by the Survey have been regularly used in the courses of instruction in geography and physiography in most of the universities and colleges and to some extent in the secondary schools. It is very gratifying to note that the maps prepared in accordance with the present high standard, and more fully adapted to such use, are coming to the attention of teachers in the graded and country schools. Teachers of schools located in the quadrangles surveyed in recent years find the corresponding topographic sheets a most practical and invaluable aid to their efficiency and success in teaching elementary geography.

*THE TRANSCONTINENTAL EXCURSION OF  
THE AMERICAN GEOGRAPHICAL  
SOCIETY*

ON the evening of August 21 there was gathered at dinner at the Harvard University Club in New York City a somewhat unusual company. Of those present forty-three were European geographers, representing fourteen different countries. There were also present about a dozen Americans, and all together were making the beginnings of acquaintance and friendship which in many cases will be lifelong. The occasion of the excursion was the completion on upper Broadway of the American Geographical Society's splendid new building. Though unannounced, it is well understood that the two months of journeying which followed was made possible through the munificence of the president of the society. The party had been organized, and the excursion was directed by Professor W. M. Davis, of Harvard University. The start was made from the Grand Central Station at 8:30 on the following morning. The special train was made up of two Pullman cars, two Pullman observation cars, a diner and a baggage car. There was also usually attached to the train a private car accompanied by some official of the several railways along which the route was taken. These officials were usually in charge of the land holdings and of the industrial operations which are now so largely promoted by our great railway systems in the west and the south. They are accomplished men and gave to the party many valuable lectures and conversations throwing light upon the development of their respective regions. A very complete outfit of maps had been provided, and the map expert of the society hung in the observation cars large and small scale maps appropriate to the regions through which we were passing daily. There were also considerable libraries, made up of the books and papers of the American members of the party and of the reports of the Geological and Geographical Surveys of the United States, and of the various commonwealths.

It would not be easy to define in a single sentence the object and work of the excursion.

The main aim, of course, was for every man to get as much first-hand knowledge about the United States as possible. This was attained in many ways. There were considerable observations from the car windows so long as daylight prevailed, and there were many stops, sometimes two or three in a day, for special features of the physical geography. Thus, in Fishkill, a little more than an hour out of New York, the party alighted from the train and ascended by the cable car to the summit of the highlands, where one of the American members interpreted the topography of the mountains, and the industrial and commercial interests of the Hudson River lowlands as they spread out northward towards Albany. At Little Falls a brief stop was made. The Dolgeville railway was ascended to the top of the cliffs and the topography and history of the Mohawk Valley were briefly described, and a representative of the state engineer's office added an account of the Barge Canal. At Syracuse the party was taken by automobiles southward from the city to see on the hills the abandoned river channels and fossil Niagaras of the closing stages of the glacial time. On the banks of the Mississippi River in the early morning the train stopped for an hour while the party scrambled to the top of the bluffs to look out over the delta of the Chippewa, and the ponded waters of Lake Pepin. The topography around San Francisco was seen by a long walk through the rift valley, marked by the earthquake movements of 1906, and also by the railway ascent to the summit of Mount Tamalpais, whose magnificent panorama includes the city, the Golden Gate, San Francisco Bay and broad stretches of the Valley of California. At Loch Ivanhoe, in Colorado, the train stopped at the western entrance of the tunnel, and the party walked over the Hagerman Pass of the Continental Divide, rejoining the train at the other end of the tunnel. At Asheville, one of the local summits of the Appalachians was reached by automobile and here lunch was taken looking out upon the wilderness of peaks and endless forests that characterize the mountains of North Carolina.

In addition to daily studies of the physical features from the train and by special excursions, a great deal of attention was given to the phases of economic and industrial development, for it is recognized by all true geographers, and it is especially emphasized by the geographers of Europe, that the science does not come to its full fruition until it has taken in, not only the lands, but the interests and relations of those who live upon them. Every one knows that a wide field for such study is open to one who crosses our continent.

From Buffalo the party visited the Lackawanna steel plant and for an hour or more were transported up and down among the various buildings and furnaces upon flat cars provided by the company. At Niagara one afternoon was devoted to the power house and the various industries, and the whole of the following day given to the falls and the gorge, with many stops and brief lectures from experts by the way. In Chicago the party inspected in squads, according to their choice, the Stock Yards, the business methods of the Sears, Roebuck Company and the map-making plant of the Rand-McNally Company. A day was spent in the great open air iron pits of Hibbing, Minnesota, where again the party was transported by many miles of zig-zagging in a train of open cars to all levels of this greatest of iron mines. A characteristic stop of forty minutes was made in sight of one of the "bonanza" farms of North Dakota, where various phases of North Dakota agriculture were explained from the observation end by experts of the state agricultural college, the audience being assembled about the rear of the train. The Europeans were vastly interested in many phases of western agriculture, familiar to them by reading, but now seen for the first time. They and the Americans as well wondered at the extent to which dry farming has encroached upon the range country in North Dakota, Montana, Washington and other parts of the arid west. A notable example of such successful dry farming was seen in central Washington. The party alighted at a little station called Almira, and were met by twenty-five or thirty automobiles

gathered from everywhere by the industry of a railway official, the main object being to see the Grand Coulee, some twenty-five or thirty miles of dry cañon once occupied by the Columbia River. On the way to this, however, a dozen miles or more of rolling country were passed, covered with splendid wheat fields, and the harvest was in progress by means of the combined reaping and threshing machines, drawn by motors or by teams of twenty horses. These crops were growing without irrigation in a region of perhaps twelve or fourteen inches of rainfall. In the Grand Coulee the party were entertained at an outdoor lunch on the ranch of a graduate of the University of Michigan, and the party learned then, as they learned many times in the west, that the graduates of our greatest universities are likely to be found wielding hard hands and wearing a pair of overalls. The after-dinner feature of this day was a good sample of broncho "busting," by the trained cowboys of the ranch. That particular day was finished by a visit to an irrigated fruit farm, where all the ladies of the region had apparently gathered, and the foreigners got a new treat in the shape of a hundred-foot table of sliced watermelon. At Tacoma the tallest member of the party, a Chicago professor, tried in vain to measure with up-stretched arm the diameter of a log which had been pulled up out of the pond, and was put to the saw under our eyes.

A few links in the excursion were made by trips over the water. At Toledo the party was entertained on the upper floor of a skyscraper, then taken across the foot of Lake Erie and up the Detroit River by boat. The blue waters of Puget Sound and the enviroing slopes of virgin forests and noble cities were likewise seen from the decks of a steamer. On the Mississippi River the party spent a happy day sailing from Memphis one hundred miles down the stream, watching the sand bars, snag boats, the means taken to protect the banks, the bordering forests, and it must be said—the lone steamer or two on waters that might carry the commerce of an empire. An old-fashioned landing was made

in the twilight, head on to the shore, but it was not exactly old-fashioned to clamber up thirty feet of sand and find at the top a brilliantly lighted train of palace cars with dinner served.

There was much of a social and educational sort. Perfection of arrangement was shown almost every day, when promptly on the scheduled moment the train pulled into the station and with equal promptness a local committee stood upon the platform, and motor cars or electric cars awaiting the party stood in the street. There was the opportunity for acquaintance with the best types of American, which was by no means small, and the American members of the party in response to oft-repeated questions as to the state of the political weather, found the same muddled and unpredictable conditions with which they had become familiar east of the Mississippi River. One of the early stops was at Ithaca, where Mrs. R. S. Tarr, bravely fulfilling the desire of her lamented husband, who was to have been a member of the excursion, opened her home for a reception. Here the party met such members of the Cornell faculty as were at home during the summer, and gained some acquaintance with one of our universities, as they did also in Chicago, in Madison and other places. Many representative people were met at dinners held in Chicago, Duluth, Portland, Salt Lake City, Denver, Chattanooga and many other places. At the dinner in St. Paul the governor of Minnesota evinced his good wit by saying that he had never expected to see so many people who knew so much about the earth and owned so little of it, while Archbishop Ireland on the same occasion made a speech which, if a little long, was every word interesting and inspiring. It was not a little interesting to the French professors who sat at his side that he was quite their equal in the finished use of their native tongue. It is hardly to be believed that one hundred representative business men of any eastern town would come out by train at six o'clock in the morning a distance of fifty miles to meet a delegation of scholars, but this was done by the men of Fargo, in North

Dakota, and the skidding of the automobiles in the wet gumbo outside of Fargo gave one a lasting remembrance of the quality of the black prairie soil. One of the pleasant memories of the Pacific coast is the hours of inspection and entertainment on the campus of the new University of Washington in a glorious suburb of Seattle. Indeed if any European came to the coast cities expecting to find things a little crude, he was obliged to alter his conceptions, for he saw paved streets, splendid buildings and innumerable beautiful bungalow homes, embowered in blossoms and greenery that never fail during the twelve months. The friendliest of social times was had in the Muir Woods, a splendid reservation of redwoods near the Golden Gate, on the day when Mr. John Muir, Mr. Luther Burbank and Mr. Fred G. Plummer were members of the party. At the University of Utah the entire party sat on the platform at the chapel service attended by a thousand boys and girls and brief addresses were made by one German, one Swiss and one American professor. Santa Fe brought the party into an old Indian and Spanish realm, and after a morning with prehistoric remains, the old adobe church of San Miguel was visited, and the ladies and gentlemen of Santa Fe gave a reception in the museum, an old Spanish building, once the governor's palace, now used for purposes of archeology. It was not all archeology, however, for the refreshments were good, the attire might have been seen in Chicago or Philadelphia, and the reception was preceded by Indian war dances, with all the accompaniments of hideous sounds, feathers and barbaric display to which the civilized Indian is still able to return. On the home journey there was a Conference on Geographical Education held under the presiding of President Alderman at the University of Virginia. Here five of the foreign and two of the American teachers of geography gave addresses on the teaching of the subject in European and American universities, which will be published and circulated by the University of Virginia. In Washington there

were a number of interesting entertainments consisting of dinners and receptions by the Carnegie Institution, the officers of the Congressional Library, the Cosmos Club and other institutions.

It will not be forgotten that men of the diligent type of the German and other European professors must have made volumes of various notes, and the crop of papers and books on America that may be expected in the coming years on the other side of the ocean may well be surprising. Records by photography were not the least. One of the strenuous Frenchmen took at least one thousand pictures, and it was ascertained by one of the Swiss members who had something of a genius for statistics and inquiry, that about twelve thousand photographs were made by the party as a whole.

One who had two months' experience of the excursion must almost say that the home life on the train was larger and more valuable than anything else. It surprised all to find that vehicles on wheels could become so thoroughly homelike, and it was the ordinary experience for members of the party returning even from the best of hotels to say: "We are glad to get back to the train."

The permanent American members of the party were about a dozen in number and represented Harvard, Yale and Columbia Universities, the University of Cincinnati, the State Normal College of Michigan, the Universities of Wisconsin and Chicago, Colgate University and the American Geographical Society. Many temporary members were with the party for one, two or three days at a time, in regions where they could serve as guides and helpers by reason of their own studies. A daily bulletin was issued on the train giving each day a full outline of the itinerary and work of the following day. There were endless conversations in the sleeping cars, on the observation platforms, in the observation parlors, in the dining cars, on platform steps, and everywhere. There were lectures in the train and off the train, indoors and out of doors, and as the party melted down together

toward the end there were entertainments, improvised Indian dances, by a young Swiss professor, occasional mock scientific papers, taking off the foibles of the party, cartoons from the skillful hands of a number of the foreigners—in brief those bits of fun which enliven weariness and make work effective. It is a tribute to the perfection of American travel that in two months, with an average party of sixty-five persons, but one meal was served on the train, outside of the dining car.

Nothing has been said in this story of the great places. Of course they were visited—the Yellowstone (six days), Crater Lake (three days), the Wasatch and Lake Bonneville, Great Salt Lake, and the irrigated fields and orchards of the valley, the Grand Cañon (the masterpiece of nature in North America), and not least, Phoenix and Roosevelt, where the Salt River Valley, the driest and hottest region of Arizona, is being turned into one of the gardens of the continent. Best of all was the acquaintance which developed and the friendships which were cemented. An eminent foreign professor in a fraternal gathering held in one of the cars before the train broke up said that he counted the excursion the culmination of his life, and he paid tribute to the universal hospitality that they had found, both among the home members of the party and the citizens of many communities, and he said that best of all, the men of Europe had come to know the American gentleman. Not only friendship must result, but broad and just views of America by a group of foreigners supremely qualified to understand. The excursion was a kind of geographical congress on wheels, and it was a means of international comity.

The final days in New York and the closing dinner at the Waldorf Astoria made a fitting end of the two months spent together. A memorial volume will be published which will include a history of the excursion by the author of this sketch, and a considerable number of geographical essays by European members of the party.

ALBERT PERRY BRIGHAM

## SCIENTIFIC NOTES AND NEWS

DR. PAUL EHRLICH, of Frankfort, and Dr. Emil Warburg, the president of the "Reichsanstalt" at Charlottenburg, have been made members of the Bavarian-Maximilian Order for art and science.

PROFESSOR J. HADAMARD, professor of analytical and celestial mechanics in the Collège de France, has been elected a member of the Paris Académie des Sciences in the section of geometry, in succession to the late Professor Henri Poincaré.

DR. PAUL MARCHAL, of the Agricultural Institute of Paris, has been elected to membership in the Paris Academy of Sciences in the section of anatomy and zoology.

THE Herbert Spencer Lecture this year will be delivered by Dr. D'Arcy Wentworth Thompson, professor of natural history, University College, Dundee, on February 13. The subject of the lecture will be "On Growth and Form."

SIR RICKMAN GODLEE, president of the Royal College of Surgeons, will deliver the Hunterian oration in the theater of the college on February 14.

PROFESSOR JAMES HAYDEN TUFTS, head of the department of philosophy in the University of Chicago, has been made chairman of the Illinois Committee on Social Legislation.

THE Geological Society of London will this year award its medals and funds as follows: Wollaston medal, Rev. Osmond Fisher; Murchison medal, Mr. G. Barrow; Lyell fund, Mr. S. S. Buckman; Bigsby medal, Sir Thomas Henry Holland, K.C.I.E., F.R.S.; Wollaston fund, Mr. W. W. King; Murchison fund, Mr. E. E. L. Dixon; Lyell fund, Mr. Llewellyn Treacher; Barlow-Jameson fund, Mr. J. B. Scrivenor and Mr. Bernard Smith.

DR. FRIEDRICH SCHOLT, of Heidelberg, known for his services in the cement industry, has received an honorary doctorate of engineering from the Technical Institute at Brunswick.

MAJOR C. H. HILLS is proposed by the council for election as the next president of the Royal Astronomical Society.

E. A. WOOD, C.E. (Cornell, '08), has resigned as professor of civil engineering in Chang Ha College, Foochow, China, and left there on December 30. He expects to travel in North China and the Philippines and then return home *via* the Suez Canal.

THE British secretary of state for war has approved of the following appointments on the army medical advisory board: as civilian physiologist, Dr. Leonard Hill, F.R.S., and as civilian sanitary expert, Dr. Henry S. Kenwood.

THE annual meeting of the Chicago Academy of Sciences was held the evening of January 14 and the following officers were elected for the coming year:

*President*—Dr. T. C. Chamberlin.

*First Vice-president*—Dr. Geo. S. Isham.

*Second Vice-president*—Dr. Henry C. Cowles.

*Secretary*—Dr. Wallace W. Atwood.

For trustee to succeed himself for a term of six years—Mr. Frederick L. Wilk.

For membership in the board of scientific governors—Dr. N. S. Davis, Mr. Albert Dickinson.

CAPTAIN ROALD AMUNDSEN will speak at the University of Wisconsin on February 10.

LIEUTENANT GRAETZ, the German explorer, according to Reuter's Agency, is making preparations for an Anglo-German airship expedition across New Guinea. The airship is to be built in Germany, but to have an English name and to be manned half by Germans and half by Englishmen. The expedition will leave Europe in October and will be absent two years. Its base will be a transport stationed off the New Guinea coast. In May Lieutenant Graetz expects to be able to make a preliminary flight in the airship from Berlin to London.

At the meeting of the Sigma Xi Society of the University of Chicago, held in the Quadrangle Club on January 7, Dr. Aaron Aaronsohn, director of the Jewish agricultural experiment station at Haifa, Palestine, gave an address on the possibilities of increasing the world's wheat supply by the introduction of wild wheat from Palestine,

which is especially adapted to growth in arid regions.

MR. A. N. JOHNSON, state highway engineer of Illinois, delivered an address before the students and faculty of the College of Engineering of the University of Illinois, on January 15, entitled "The Present Status of Road Work in Illinois."

MR. DONALD F. MACDONALD, geologist of the Panama Canal, spoke to students of the department of geology of Columbia University on January 17 on "The General Geology of the Panama Canal Zone."

At the recent meeting of the American Society of Zoologists at Cleveland, Ohio, the following resolution was presented and approved by the society:

In the death of Nettie Maria Stevens on the fourth day of May, 1912, this society loses one of its ablest members, one whose work upon the relation of the chromosomes to the transmission of sexual characters is of fundamental value. Entering upon these painstaking studies in her later years, she soon attained to a position of leadership in a peculiarly difficult field of research.

Her achievements were a credit to Bryn Mawr College, from which she obtained the well-deserved honor of the degree of doctor of philosophy, and in the world of science her place among cytologists is both secure and high.

DR. THOMAS VOLNEY MUNSON, who while engaged as a nurseryman at Dennison, Texas, made valuable experiments on the breeding of fruits, especially in viticulture, died on January 21, aged seventy years.

THE Earl of Crawford, who built an observatory at Dunecht and made contributions to astronomy, died on January 30.

THE U. S. Civil Service Commission announces several examinations for positions under the Department of Agriculture on February 24 and 26, including forest pathologist at a salary from \$1,980 to \$2,400; assistant forest pathologist, from \$1,440 to \$1,800; assistant in xylotomy, at \$1,000; assistant in soil surveying, at \$960 to \$1,200; assistant in forest management, at \$1,400; examiner of

surveys, at \$1,200 to \$1,500, and assistant irrigation engineer at \$1,200 to \$1,600.

THE New York State Forestry Association was organized at a convention in Syracuse on January 16, attended by some fifty representatives of the various parts of the state. This association has for its object the fostering of genuine forestry progress in the state of New York, and in this enterprise it hopes to represent effectively the spirit of forest conservation in the state at large and of the various associations interested in the welfare of the forests of New York. During the convention valuable papers on forestry subjects were presented and the nearly fifty guests at the evening banquet were addressed by President Drinker, of Lehigh University, president of the American Forestry Association. The president of the association is Dr. Nathaniel Lord Britton, director of the New York Botanical Garden and Museums, and its secretary, Dean Hugh Potter Baker, of the New York State College of Forestry at Syracuse University.

THE State Microscopical Society of Illinois held its annual meeting on January 9, at which the following officers were elected:

*President*—Albert McCalla, Ph.D.

*First Vice-president*—Walter F. Herzberg.

*Second Vice-president*—Frank Harmon.

*Treasurer*—Frank I. Packard.

*Corresponding Secretary*—N. S. Amstutz.

*Recording Secretary*—V. A. Latham, M.D., F.R.M.S.

*Trustees*—M. D. Ewell, M.D., LL.D., D. L. Zook, S. S. Graves, M.D., B. U. Hills, H. F. Fuller.

The conjoint soirée with the Chicago Academy of Sciences set for February 12 has been postponed to March 12 on account of the extensive changes in the electric lighting of the academy building from the direct to the indirect system not being completed.

THE president and fellows of Harvard College voted, on January 27, to establish the Harvard University Press, for the publication of works of a high scholarly character. For some years the university publication office, besides printing the catalogues, department

pamphlets and other official documents, has found it possible, in spite of its limited resources, to issue from time to time a few special works, until it now publishes seven periodicals and more than eighty books, ranging from treatises on Indic philology to practical directions for American lumbermen. To organize and extend this activity, so as to make the university properly effective as a publishing center for scholarly books, is the object of the new foundation. The press announces several noteworthy volumes as in preparation, including books by the late Professor James Barr Ames, of the Law School, and by Professors George Foot Moore, Eugene Wambaugh, Arthur E. Kennelly, George L. Kittredge, Charles H. Haskins, George A. Reisner and W. B. Munro. The board of syndics who will decide on the books to be published are Robert Bacon, fellow of Harvard College, chairman; George Foot Moore, professor of the history of religion; Arthur E. Kennelly, professor of electrical engineering; George L. Kittredge, professor of English; Charles H. Thurber, member of the firm of Ginn and Company; Edwin F. Gay, professor of economics and dean of the graduate school of business administration, and W. B. Cannon, professor of physiology. The director of the press is Charles Chester Lane, for the last five years publication agent of the university.

It will be remembered that after the conference for the discussion of theories of radiation, held in Brussels in 1911, Mr. Ernest Solvay, of that city, established an International Physical Institute with an endowment of \$200,000. An article by Professor E. Rutherford, in *Nature*, states that part of the income is to be devoted to the foundation of scholarships for the promotion of scientific research in Belgium, part to defray the expenses of international meetings to discuss scientific problems of interest, and the residue to be awarded in the form of grants to scientific investigators to assist them in their researches. For the first year, which terminates on May 1, 1913, a sum of about 17,500 francs is available for the latter purpose. It is the intention of the committee each year to give

grants for special lines of work. As the first international meeting was engaged in the discussion of the theories of radiation, it is proposed this year to assist preferentially researches on the general phenomena of radiation, comprising Röntgen rays and the rays from radio-active bodies, general molecular theory, and theories of units of energy. The grants will be awarded without distinction of nationality by the administrative committee of the institute on the recommendation of an international scientific committee. The administrative committee is composed of Professors P. Heger, E. Tassel and J. E. Verschaffelt, of Brussels; the scientific committee is composed of H. A. Lorentz (Haarlem), Mme. Curie (Paris), M. Brillouin (Paris), R. B. Goldschmidt (Brussels), H. Kamerlingh-Onnes (Leyden), W. Nernst (Berlin), E. Rutherford (Manchester), E. Warburg (Berlin), and M. Knudsen, secretary (Copenhagen).

As the result of a conference which was held under the auspices of the U. S. Bureau of Mines last September, of men who are interested in the saving of the lives of miners, there has been formed a society known as the American Mine Safety Association, with headquarters at 40th and Butler Streets, Pittsburgh, Pa. This association, which is now enrolling among its members the leading coal and metal mine operators, mining engineers and mine safety engineers of the country, has for its purpose the conservation of the lives and health of the miner and a reduction in property loss due to explosions or fires in mines. It will attempt to place before the miners standard methods to be used in rescue work and in first-aid to the injured. The work of the Bureau of Mines in reducing the number of deaths in the mines has led to the adoption of many different types of rescue apparatus, such as the oxygen helmets which the rescuers wear in a gas-filled mine, and also to the use of many different methods of resuscitation and first-aid to the injured. Hundreds of mines within the last three or four years have been equipped with rescue apparatus, rescue corps and first-aid corps.

Many of these men who are called upon in emergencies have developed their own ways of doing things and it is the opinion of the organizers of this association that the most efficient methods and apparatus should be found through actual use and recommended to the mining industry as a general standard. Mr. H. M. Wilson, the engineer in charge of the experiment station of the Bureau of Mines at Pittsburgh, has been selected as chairman of the executive committee of the association and has been instructed to carry on the work of organization. Membership in the American Mine Safety Association is open to any individual, firm, corporation or society interested in the reduction of the loss of life and property in mines.

THE faculty of medicine of Harvard University offers a course of free public lectures, to be given at the Medical School on Sunday afternoons at four o'clock, as follows:

January 5—"Preventive Medicine in relation to Industrial and International Concord," Dr. Charles W. Eliot.

January 12—"The Care and Feeding of Young Children," Dr. John Lovett Morse.

January 19—"Leprosy and its Care in Massachusetts," Dr. Charles J. White.

January 26—"What the State Board of Health is doing to protect the Health of the Citizens of Massachusetts," Dr. Mark W. Richardson.

February 2—"The Sexual Instinct—its Abuse and Control" (to men only), Dr. Edward H. Nichols.

February 9—"The Responsibility of the Community for the Prevalence of Venereal Disease," Dr. Hugh Cabot.

February 16—"Dangerous Effects of Patent Medicines," Dr. David L. Edsall.

February 23—"Fresh Air, Exercise and Physical Condition," Dr. Edward H. Bradford.

March 2—"The Bladder Ailments of Men in Later Life" (to men only), Dr. Paul Thorndike.

March 9—"Ophthalmic Catastrophes," Dr. Myles Standish.

March 16—"How to cultivate Emotional Poise in an Emotional Age," Dr. George L. Walton.

March 23—"The Rise of Experimental Medicine," Dr. Howard T. Karsner.

March 30—"Tumor Diseases Peculiar to Women" (to women only), Dr. William P. Graves.

April 6—"The Management of Scarlet Fever and Measles," Dr. E. H. Place.

April 13—"The New State Psychopathic Hospital," Dr. E. E. Southard.

April 20—"The Effect of Occupation on the Hearing Power," Dr. Clarence J. Blake.

April 27—"The Hygiene of Pregnancy" (to women only), Dr. Franklin S. Newell.

May 4—"Treatment of some Emergencies of a Surgical Nature," Dr. Howard A. Lothrop.

May 11—"The Preservation of the Natural Teeth," Dr. Charles A. Brackett.

May 18—"Future Lines of Investigation of Infectious Diseases," Dr. S. B. Wolbach.

AMONG the features of the British Association meeting in Birmingham in September next, as noted in the *London Times*, will be a number of popular science lectures. In view of the central position of Birmingham a large attendance of members is expected, and a local fund of not less than £6,000 is being raised in order that the arrangements may be worthy of the city. A private canvass has already obtained the promise of nearly £4,000, and an appeal for further subscriptions will be made at an early date. Twenty-seven years have elapsed since the last visit of the association to Birmingham. The meeting this year opens on Wednesday, September 10, and continues until the 17th. On the first day, in addition to various meetings, there will be a reception of the foreign guests and in the evening the president, Sir William White, will deliver his inaugural address. The program for Thursday, September 11, includes sectional meetings, a conference of delegates, a garden party, a popular science lecture and a reception. Next day the morning is to be devoted to sectional meetings. In the evening a discourse will be addressed to members, and there is again to be a popular science lecture to the general public. Saturday will be given up to excursions which are being arranged by a special sub-committee, including the principal local archeologists, geologists and botanists. On Sunday there will be services at the Cathedral and other places of worship. Sectional meetings will again be held on the following day, and in the afternoon there is to

be a public function at the university. The local committee will entertain the distinguished visitors at night, probably at a theater. Tuesday, September 16, will be devoted to sectional meetings in the morning, and a conference of delegates and a garden party at the Edgbaston Botanical Gardens in the afternoon. In the evening there is to be another popular science lecture and a discourse to members. On the following day the meeting closes.

#### UNIVERSITY AND EDUCATIONAL NEWS

THE regents of the University of Wisconsin have decided to ask the state legislature, now in session, for \$1,000,000 to be appropriated in sums of \$250,000 a year for four years, in order to provide and equip dormitories for men, a men's commons and union and a student infirmary. They have also voted to request the continuance of the present appropriation of \$300,000 a year for the construction and equipping of academic buildings. For the further development of university extension work, the regents desire an increase of \$25,000 a year. Owing to the reduction in the assessed valuation of personal property, resulting from the adoption of the income tax in Wisconsin, the university's fund for current expenses provided for by the three eighths of a mill tax, has this year fallen below the amount anticipated. The regents, therefore, have requested that the sum of \$92,380 be appropriated to make up this year's decrease; that \$175,000 be provided for next year's decrease, and \$225,000 for the following year's decrease.

It appears from reports in the daily papers that Professor Willard C. Fisher, of Wesleyan University, known for his effective advocacy of legislation on behalf of the laboring classes of Connecticut, has been dismissed from his chair at Wesleyan University for stating that religion would benefit from the closing of churches for several years.

FORMER Dean W. A. Henry, of the College of Agriculture of the University of Wisconsin, has presented his private library to the agricultural college. It will be maintained

largely for the use of the dean and director of the college and the station.

THE whole staff of the college of medicine and surgery of the University of Minnesota having resigned, the regents have named the following committee to consider and make recommendations concerning the reorganization of medical teaching in the university: Dean Wesbrook, Drs. Moore, Green, Wilson (of Rochester), Tuohy (of Duluth), and Bratrud (of Warren), and the president of the university.

MR. ALFRED KNIGHT CHITTENDEN, forester in the U. S. Indian Service, Department of the Interior, has been appointed assistant to the director of the Engineering Experiment Station and lecturer on timber and timber resources in the College of Engineering of the University of Illinois.

PROFESSOR EDWARD C. ELLIOTT, head of the education department at the University of Wisconsin, has refused the offer of the presidency of the University of Idaho recently made him by the regents of that institution.

#### DISCUSSION AND CORRESPONDENCE

##### CONN'S "BIOLOGY"

TO THE EDITOR OF SCIENCE: In the last number of SCIENCE (December 28) I notice a review of Conn's "Biology," by M. M., in which the reviewer draws parallels between the subject in hand and some other sciences. It would seem that the examples selected were ill chosen to meet the point at issue. But this may be due to the fact that others look upon biology differently from the reviewer.

Biology, being the study of living things, must be concerned with either plants or animals. A book written by either of the corresponding scientists is likely to be more accurate in all details, within his field, than is a book written by a scientist engaged in the other of the two fields. To cover accurately both divisions of the subject requires a breadth of view, and a degree of detailed knowledge in each field, not often combined in a single individual; especially in these days of high specialization.

How much better will a sophomore understand the general conditions governing respiration after reading this book, in which the references in index are to animal respiration only, than from selected portions of two books showing that exchange of gases takes place both in plants and in animals?

Or what will a student understand from the statement (p. 226) that "in plants the supporting structure is, as a rule, developed better than in animals." Wherein is the oak "better" than the horse, in respect to its supporting structure?

Again what would a thinking student make of the statement (p. 234), "there are other materials made by the plants, like wood and leaves, which can not serve as food for animals," when he sees boring insects in wood, reads of beavers and their winter supply of tree trunks, and observes animals grazing on the leaves of plants?

And if any members of a domestic science class should notice the definition of yolk, page 249, as "deutoplasm (Gr. *deuteros* = second + *plasma* = substance), deposited in the egg for the nourishment of the young," when in all their cooking experience concerning eggs they are taught that the yolk is at the center, while albumen or "white of the egg" is deposited about this—what conclusions would they draw from "biology"?

No doubt a number of these misstatements are chargeable to the printers, but they should be eliminated in a second edition.

In the review signed M. M. one side of the subject is presented; in the above note, another viewpoint is taken—botany and zoology as constituting biological science.

FREDERICK H. BLODGETT

TEXAS EXPERIMENT STATION

As this work, lately reviewed in *SCIENCE*, will probably be used in many colleges, it may be well to point out a paragraph on distribution which certainly needs amendment:

The high mountain ranges are perhaps the most effectual barriers of all. Practically no animal or plant is able to cross over the higher mountain ranges. The Rocky Mountains effectually separate

the eastern from the western slope, and the life on the two slopes of these mountains is quite different, though the climate may be much the same (p. 381).

It would be difficult to write anything more misleading. The life on the two slopes of the Rocky Mountains is not "quite different," except when climatic (especially moisture) conditions differ on the two sides. The statement as given is nearly true for freshwater fishes in Colorado, but quite untrue for the great majority of plants and animals.

Several other things in the book should be corrected. It is certainly misleading to write "primrose," instead of evening primrose, for *Oenothera* (p. 357). I do not understand why *Onychophora* (p. 378) are said to be centipedes. These and other such things are of course small matters in comparison with the large amount of excellent material in the book; but there should be no flies in the biological soup prepared for college students.

T. D. A. COCKERELL

UNIVERSITY OF COLORADO

#### THE REFORM OF THE CALENDAR

TO THE EDITOR OF *SCIENCE*: With reference to my article on the reform of the calendar published in your number for May 6, 1911, Vol. XXXIII, pp. 690-2, I desire to call the attention of those who took part in the discussion at that time to further developments in the matter.

In the December number of the *Esperanto Scienca Gazeto*, published in Paris by Hachette & Co., Ch. Verax, editor, we are told that the Swiss government actually appointed the commission referred to in my article and since that time have received 30 different projects for the reform of the calendar, 14 of which were written in Esperanto and the other 16 in seven different national languages.

The commission is still open for additional proposals and it is to be hoped that all those who took part in the discussion in *SCIENCE* will send their proposals without delay to the address "Conseil federal" or "Schweizerischer Bundesrat" (Federal Council), Bern, Switzerland.

It is also to be hoped that all persons who approve of the proposition to reform the calendar will write to the Swiss Federal Council immediately, expressing their approval of and giving their ideas on the subject.

J. M. CLIFFORD, JR.

#### SCIENTIFIC BOOKS

*Elementary Entomology.* By E. DWIGHT SANDERSON and C. F. JACKSON. Ginn & Co. 1912. Pp. vii + 372.

"During recent years there has been an increasing demand for short courses in elementary entomology. For several years past the authors have been endeavoring to present such courses to their students, but have encountered the difficulty that no text-book was available which met their needs. This book is, therefore, the author's effort to furnish such a text for beginners. . . ."

In a brief introduction the authors point out the important rôle insects play in the transmission of disease, and emphasize their importance as agricultural pests. Their explanation of why insects are so numerous in individuals and in species is not clear. "The immense number of insects, both of species and of individuals, is undoubtedly due to their varied structure which enables them to live under all possible conditions. . . . Thus the insects possess such diversity of structure and habit that they are able to live under all external conditions, and on account of their immense numbers they have been able to adapt themselves to a changing environment which would have entirely obliterated classes or species few in number." In other words, insects are numerous because they are diverse in structure and are diverse in structure because they are numerous.

The book is divided into three parts: I., The Structure and Growth of Insects, 62 pages; II., The Classes of Insects, 208 pages; III., Laboratory Exercises, 84 pages.

In Part I. a brief chapter is devoted to the near relatives of insects. The figure of the spider illustrating the arachnida is from a

photograph taken at such an angle that it does not show the division of the body into cephalothorax and abdomen mentioned in the text, but does show the modified antennæ (chelicerae) which, according to the text, are not possessed by Arachnida. The treatment of the Myriapoda is inadequate even for an elementary text. No distinction is made between the Diplopods and Chilopods, and while the figure shows a Diplopod with two pairs of legs to each segment, the text says that "each segment bears a pair of legs." The same statement is repeated in the table on page 9.

The twenty-four pages devoted to the anatomy of insects show the same evidence of hasty and careless work. The original figure of a typical maxilla of the grasshopper (Fig. 11) omits the cardo. We are told that the mandibles are always essentially biting organs, though many of the copied illustrations show their piercing form. We would agree with the authors that the mandibulate mouth-parts of the different orders are "apparently homologous," but what reason is there for believing that the types of suctorial mouth-parts are "entirely dissimilar in structure and origin"? However, it is consistent with such a belief that the illustrations of the mouth-parts of the mosquito and horse-fly (18 and 20), "good examples of the piercing type," should be labeled without further discussion, according to radically different interpretations, and that Fig. 15 is referred to on page 18 as of dipterous mouth-parts, though it is correctly labeled as hemipterous.

We are told on page 24 that "the wings are strengthened by numerous thickenings called veins, whose number and position form the basis of the classification of families, genera and species." Then, important as the subject would seem to be, a half paragraph, accompanied by an incorrectly labeled figure of the wing of a house fly, is devoted to a summary of the Comstock-Needham system, while in the systematic portion thirteen dipterous wings labeled according to this same system are illustrated and the key to families uses another system which is not even mentioned—not to say *explained*—in the text.

In the chapter on growth and transformations of insects the authors fail to make very clear the real distinction between complete and incomplete metamorphosis. "The transformation of the butterfly from the caterpillar is a *complete* one, and is known as a complete metamorphosis. The growth of the grasshopper, on the other hand, is gradual and presents no striking changes, and is known as *incomplete metamorphosis*." In view of this definition the elementary student will be at a loss to understand why later in the book the Aptera are said to have no metamorphosis. As illustrations of the types of metamorphosis an account is given of the life history of the squash-bug, differential locust, tent caterpillar and spiny elm caterpillar. The account of the squash-bug is apparently from first-hand observation, the others are poorly digested from Morgan and Weed. A confusing error occurs in the account of the differential locust; Fig. 66 shows five grasshopper nymphs of various sizes and the legend says "First three stages of the nymphs of the differential locust"; Fig. 68 shows the last two. The text says that the different stages will be found in Fig. 67, which is a picture of an egg mass.

Part II., The Classes of Insects, opens with a chapter on classification which the authors could improve greatly by adopting a more direct and concise style.

The orders are then taken up in the usual sequence and treated very briefly. There is a superabundance of good figures, mostly borrowed, and the text often takes the form of a running comment on the pictures in the style of a stereopticon lecture, rather than a connected account to which the illustrations are subordinate. Of the 496 figures in the book, 406 or over 80 per cent. are borrowed from other works or are from borrowed photographs. Is there not danger that the elementary student might get the idea from these borrowed pictures that entomology is a second-hand science? Most of the figures are good, but some could be greatly improved. Some of the cuts of butterflies attributed to Fiske are very poor; the specimens seem to have been slightly

out of focus and the negatives thin and flat. The bronze copper butterfly is certainly not so rare that there is any excuse for using a photograph of a mutilated specimen. Fig. 116, labeled "A Myrmeleonid, the adult of the antlion," is a Chrysopid.

This portion of the work contains many misstatements, only a few of which can be noted here. The long rows of tree-cricket eggs in raspberry canes are still credited to *Oecanthus niveus* in spite of the recent work of Parrott (Fig. 110). In speaking of the armored scales, the surprising statement is made that "with the first molts the female loses her legs and eyes, and the body becomes a mere mass of yellowish protoplasm with long thread-like mouth-parts," etc. The American rose-slug is given one generic name in the figure (Fig. 385) and a different one in the text; a similar slip occurs in the case of the screw-worm fly (Fig. 376). On page 243 it is stated that most of the larvæ of the Hymenoptera live within the food, exception being made of the first two families (Tenthredinidæ and Siricidæ). This is an inaccurate statement in the case of the larvæ of most of the aculeates as well as many parasitica. The remarks upon the ovipositor of Siricidæ apply only to that family in the strict sense, and not at all to the other families, which we are forced from the keys to assume are included under the term Siricidæ. The only definition of the stigma that is found appears in the statement under Cynipidæ that they lack "the dark spot or stigma toward the end of the anterior margin of the wings." The largest Braconidæ are stated to be not over one eighth of an inch in length, and the largest Proctotrypidae not over one twenty-fifth of an inch; an astonishing statement in view of the fact that the typical genera *Bracon* and *Proctotrypes* both contain species measuring 10 mm., not to mention still larger common forms in other genera.

In Part III., Laboratory Exercises, six chapters are devoted to the external and internal anatomy of insects, the comparison of different types of arthropoda and of insects, the study of mouth-parts, etc. These exercises

are carefully arranged, are well written and apparently have been tried out with elementary classes. These chapters form the most satisfactory part of the work.

In chapter XXII., Classification of Insects, keys are given by which the student is supposed to be able to determine insects to orders and families. Here the authors have not been so fortunate.

The classification of the Hymenoptera adopted (p. 319) is woefully inadequate even for a very elementary text, and does not represent any of the progress made within the last quarter of a century. Granting the diversity of opinion that still prevails in regard to many points of the classification of this order, there is, however, much that has been done within that time that can not properly be ignored.

The inclusion of saw-flies, gall-flies and parasitic Hymenoptera in one suborder, as contrasted with all the remaining groups (aculeates) in another, is indefensible. The inclusion of Lydidae and Xyelidae in the Tenthrinidae, and of Cephidae, Xiphidriidae and Oryssidae in with Siricidae has no longer any justification. On the other hand, the best founded work on ants to-day recognizes but a single family, comprised of five subfamilies. It would seem that this position might at least be advantageously maintained in an elementary key which, for the sake of brevity, omits mention of many important families. Neither this course was followed nor the alternative of including five family groups. On the contrary, three family names appear in the key, Poneridae, Myrmicidae and Camponotidae. The Dorylidae, relatively unimportant in this country, as well as the very important Dolichoderidae, are not mentioned. The latter includes the economically important Argentine ant (referred to in the text on page 259 as belonging to the Myrmicidae) as well as several very common North American forms which the casual student is far more likely to frequently meet with than he is with any Poneridae. By the key all the Dolichoderidae would fall into the so-called Camponotidae, with which they have no closer relation than

have any of the other groups of ants. The term *Camponotidae* for the group containing the genus *Formica* is used for Formicidae, despite the fact that the superfamily name Formicina based on that genus is used directly above it—a rather astonishing neglect of the established customs as well as codes of nomenclature.

There may be some excuse for omitting from the key such families as Evaniidae, Stephanidae, Trigonalidae, Sapygidae and Melinidae, but to be consistent the equally uncommon Masaridae should be omitted. But why is there no place provided for the Lariidae, Nyssonidae, Philanthidae, Pemphredonidae and Crabronidae, all of which are abundant in species and individuals? The majority of the species belonging to these families fall, according to the key, in the Bembecidae, the others in Sphecidae, but the division is along a line that can make no pretense of being natural or even convenient.

It might also be noted that there is no provision made for wingless Hymenoptera in the keys and that therefore the wingless parasitic species, the worker ants and female Mutillidae can not be classified. The term Psammocharidae is used for Pompilidae or Ceropalidae of older authors, but the name Proctotrypidae is not replaced by Serphidae.

The whole principle of key construction with the intention of omitting "less important" forms is open to grave objection. The result is that the student chancing upon a specimen of a non-included group (and in the present case such specimens will be legion) ends in running it out to a family to which it does not belong, and confident in the correctness of his labors and unsuspecting the untrustworthiness of the key, has it impressed upon his memory as one of the types of that family. A far better method, in fact the only defensible method where keys are presented, is to make them complete enough to provide correctly for *all* forms coming within their scope, and then if deemed desirable rare or less important groups may be bracketed or set in special type. Otherwise it were better the tables were omitted altogether.

The key to the families of Diptera is written by an eminent authority in that group and will doubtless prove one of the most valuable parts of the book. Unfortunately some of the smaller families are omitted. The most serious drawback, so far as the present work is concerned, is the fact that the old and complicated Schinerian system of wing venation nomenclature is used, but nowhere explained, the explanatory figures of wings of Diptera, as in the other orders, being lettered by the Comstock-Needham system. The wing of *Blepharocera* is figured, although the Blepharoceridæ are omitted from the keys and the text does not explain that the intricate maze of intersecting lines are not veins, but folds in the wing membrane. They will surely puzzle any one who does not appreciate that fact. "Second boscal" cell (bottom of p. 323) is probably a misprint.

The wings of Hemerobiidæ are not ordinarily opaque, as stated in the table on page 307. Only one family of Trichoptera is recognized, although all authorities to-day would agree in recognizing more. Only one family of Thysanoptera is recognized, despite the fact that modern authorities recognize two suborders and several families.

In the key to families of Hemiptera the first category is "wingless insects with fleshy unjointed beak," its alternative is "winged or wingless insects, with a jointed beak," but under the latter is a subheading which provides for wingless insects with the beak wanting! Further, the beginner would often experience difficulty in recognizing the jointed character of many Coccid beaks.

The Aphidæ are differentiated from Aleyrodidæ and Coccidæ by having "long and slender legs and transparent wings," while the two latter are said to have "legs short, wings usually opaque." It is hardly necessary to mention the many legless Coccidæ, as well as the long-legged forms (*Orthesia*, etc.).

In the table to Coleoptera the majority of families are omitted altogether, and so are very many in the Lepidoptera. In the discussion of the latter order no mention is made of a division into two suborders Jugatæ and

Frenatæ, but the *butterflies* and *moths* are said to form two main divisions of the order. The wing of *Hepialus*, however, is figured and the jugum noted in the legend. Such an insufficient statement as "subcosta and radius of hind wing connected by a cross-bar" is noted in the characterization of Sphingidæ.

The work closes with chapters on collecting and preserving insects, which will be of great value to the student.

The book is well printed on good paper and the illustrations, as a rule, come out well; when properly revised, it will make a welcome addition to the rapidly growing list of entomological texts, from which the teacher can choose the one best suited to the needs of his students.

#### *Dynamic Meteorology and Hydrography.*

Part I., Statics. By V. BJERKNES and J. W. SANSTRÖM. Quarto. Pp. 234. Part II., Kinematics. By V. BJERKNES, TH. HESSELBERG and O. DEVIK. Quarto. Pp. 175 (with atlas of 60 charts). Carnegie Institution, 1911.

The object of this treatise is to develop practical methods for the systematic study of the pressure, temperature, humidity, density and velocity of the atmosphere. On account of the difficulty of solving the differential equations of a viscous gas the methods are almost entirely graphical, elaborate tables being given that obviate the necessity of even ordinary integration. In Part I. it is assumed that the conditions of equilibrium are fulfilled along every vertical line. From the records of a balloon sent up with self-registering instruments for pressure, temperature and humidity, it is therefore possible to calculate the pressure and density at different heights. For facility of calculation the authors divide the atmosphere into sheets each about 1,000 meters thick, beginning at sea level, and find the average density and temperature of each sheet. To allow for the humidity and still use Boyle's law, as for dry air, a virtual temperature is used that is derived from the

humidity and the actual temperature. In some cases the authors prefer to use, instead of the sheets, the heights of the surfaces of equal pressure drawn at intervals of one tenth of an atmosphere. Less accurate results can also be found from observations at the earth's surface, assuming average values for the changes as one ascends vertically. By these two methods it is possible to draw level surfaces and vertical sections that show the pressure and density at different parts of the atmosphere. If the equilibrium were exact the surfaces of equal pressure, of equal density and the level surfaces would coincide. The more these surfaces differ from each other the greater the tendency to motion. Similar considerations are discussed for the oceans, but these do not at present appear to have the same importance as the atmosphere. The second part takes up the representation of velocity. From observations of small balloons the horizontal velocity in different localities and at different heights can be found. These results are averaged with respect to height for the sheets of the atmosphere that were used in the first part of the work. The lines of flow can now be drawn for each sheet and also the curves of equal velocity. In some cases the authors use "isogonal" curves, namely, curves of equal direction of velocity. The use of these curves to solve differential equations is credited to Sandström. It appears, however,<sup>1</sup> to be due to Massau, who called them "isoclines." Towards the end of the volume these diagrams are used to deduce the vertical motion of the atmosphere under the assumption that momentum is a solenoidal vector, a downward velocity indicating precipitation. A supplement of 60 excellent maps comprises conical projections of the earth's surface showing the contour lines, in 24 sheets, and examples of the preceding methods applied to actual cases. The middle of Part II. contains an elegant study of two dimensional vector fields and of the graphical treatment of the operations which occurs in the differential equations of hydrodynamics.

<sup>1</sup> See D'Ocagne, "Calcul Graphique."

It is to be hoped that the authors will complete their work by a third part, on the dynamics of the atmosphere, as distinct from the kinematics, including Professor Bjerknes's own work on this part of the subject, and also extend the period of six hours; which is the limit of their prognostications, at present. A fuller treatment of the thermodynamics of the atmosphere would also be desirable.

F. R. SHARPE

*The Theory of Experimental Electricity.* By W. C. D. WHETHAM, F.R.S. Second edition. Cambridge, The University Press; New York, G. P. Putnam's Sons. Pp. xi + 340. \$2.50 net.

It gives us great pleasure to welcome a new edition of Mr. Whetham's text-book. This work presents the subject of electricity as a living science and is characterized by a wonderful freshness of treatment. It is thoroughly up to date and includes such matters as the thermodynamic theory of electrolytic cells, conduction through gases, radioactivity and the electron theory. Although of necessity brief, the treatment of these subjects is quite accurate. Excellent judgment has been shown in the choice of material and the newer branches of the science are exhibited in their proper relationship to the old. One of the striking features of the book is the combination of simplicity and accuracy in the proofs used in establishing the important principles of the science.

We regret to observe that two blemishes which we noticed in the first edition have not been removed. The treatment on pp. 35 et seq. of the force due to a charged plane as though the charge resided on both sides of the plane is cumbersome if not actually misleading. The proof on page 105, of the mechanical force on a current due to a magnetic field, is fallacious as it stands; although it is made to give the right result. This matter could easily be rectified without changing the method. We also think that it is high time that Franklin's proof that the charge resides in the dielectric were dropped from the text-

books. The inference from the experiment is fallacious; moreover the experiment does not work if the dielectric is dry and low potentials are employed, or, in any event, if the dielectric is a gas or a vacuum.

Despite these minor blemishes the book is an excellent one. The style is admirable and the whole treatment is calculated to inspire the interest of the student. We can thoroughly recommend its use with classes which have already had a general course in physics.

### SPECIAL ARTICLES

#### RELATIONSHIP OF THE INDIAN LANGUAGES OF CALIFORNIA

ANTHROPOLOGICALLY California has always been noted for its linguistic diversity, which has been accepted as being greater than that of any other part of the world. Since Powell's standardizing classification, which allotted 22 distinct families of native languages to the state, only one consolidation, that of Shasta and Achomawi, has been positively asserted and generally accepted. Two or three other pairs of languages have for some time seemed to be probably each reducible to a common origin; but the specific similarities determined were weakened by the frequent occurrence of both lexical and grammatical resemblances between many other families which there was no justification for connecting genetically. These grammatical resemblances have been several times discussed by us and attributed to the inter-influence of distinct families, due to geographical contact. The lexical similarities we have assumed, in all but a few cases, to be the result of borrowing. It became clear that until the degree and extent of this mutual influencing and borrowing among unrelated languages were more precisely ascertained, the relationships suspected in the few instances referred to were capable of explanation through such borrowing on a slightly more intensive scale, and would therefore never advance beyond the stage of probability. For this reason we undertook some time ago a comparison of more than 200 stem words in

all the languages and dialects of California so far as material was available. From the time the material began to be assembled, some interesting results as to the character and scope of the borrowing of words commenced to appear; but after analysis of the collected information had progressed beyond a certain point, it became apparent that the only satisfactory explanation of the resemblances between certain languages was genetic relationship. On the basis of these indications the grammatical information extant on the same languages was reexamined, and in every instance was found strongly confirmatory. Lexical and structural similarities coinciding and being relatively abundant, true relationships have been accepted as established. The new larger families and their components are:

Penutian, comprising the groups formerly known as Maidu, Wintun, Miwok, Costanoan and Yokuts. This is a relatively large and compact family, occupying practically the whole of the drainage area of the great valley of California.

Hokan, comprising certainly Shasta, Chimariko and Pomo, probably Karok, and possibly Yana. The territory of this family is in the hill country to the north and west of the Penutian, and is more irregular.

Ritwan, comprising Yurok and Wiyot. No new proof on the previously suggested possible relationship of these two languages was obtained, except the negative evidence of complete lack of resemblances of both to any other family, which of course increases the weight of the similarities between the two, insufficient though these may yet be for absolute demonstration.

The number of distinct families in California is thus reduced from 21 certainly to 15 and possibly to 12.

Owing to the absence of one of the undersigned in Asia at the present moment, some time must elapse before our material and conclusions can be finally revised and published. For this reason the present announcement is issued.

A. L. KROEBER

## CRITICAL CRITERIA ON BASIN-RANGE STRUCTURE

As commonly regarded, basin-range mountains constitute an orogenic type by themselves; novel, isostatic, youthful appearing. The hypothesis of their structure is one of the most brilliant concepts in the history of American geology; at the same time it is one of the most fanciful, as the severe testing of a generation amply proves. Singularly enough, the theory had its birth in a district where even its fundamental form seems to be entirely without representation.

At this day and distance the extension of the hypothesis to all the so-called fault-block mountains of the arid regions appears to be not only too broad a generalization, but quite unfortunate. Although I should not wish to be the first to make so sweeping an assertion as lately was done by Dr. Spurr, that no one has ever seen the fault-lines blocking out the desert ranges, his statement is almost literally true, as all recent critical evidence on the subject fully attests.

The attractive feature of Gilbert's theory of basin-range structure was of course the strong support it was thought to give to the now famous hypothesis of isostasy. Concerning some of the fundamental premises, I long ago entertained serious doubts. It has since been fully shown that there was decided error in determining the degree of completeness of the compensation that invalidated the conclusions.

With the challenge of the basin-range hypothesis there has come a demand for citations of concrete examples in support of the theory. Thus far, after the elapse of a full decade and after frequent repetition of the demand, the evidence has not been forthcoming. The Cricket Range, in Utah, recently described in this journal as furnishing a key to the problem, emphasizes this shortcoming. It is not the mere display of profound faulting that is the main desideratum. Abundant evidence of this kind is readily found in nearly every one of the desert ranges. In the majority of cases such faultings are found to have no relations to the present orogeny. Where, according to the hypothesis, the bordering faults should be they are not; but when found they are usually

miles out on the intermont plains. The present sharp meeting of mountain and plain is now explained by causes other than dislocation, through ordinary stream-corrasion according to Paige, or through sheet-flood erosion as urged by McGee. Under a title of "Locus of Maximum Lateral Deflation in Desert Ranges" I have called attention to its eolative origin.

By displacement are explained the steep truncations of the transverse ridges of many desert ranges. That these levelments are really fault-planes bounding the mountain-blocks will have to be more strongly supported than it is now, by direct and unquestionable evidence, before the assertion can be accepted. These rows of truncated ridges seem rather to mark the lines of battle between the planar advance of eolic degradation from the desert side and the normal stream-corrasion of the more moist mountain areas.

In the light of the recent advances in our knowledge of the prodigious amount of deflation which takes place under climatic conditions of aridity it appears that the generally accepted hypothesis of basin-range structure will have to be abandoned and the origin of the desert mountains ascribed to eolic erosion mainly, rather than to local tectonic displacement.

CHARLES R. KEYES

NOTE REGARDING THE RELATION OF AGE TO FECUNDITY<sup>1</sup>

IN his valuable book on "The Physiology of Reproduction" Marshall,<sup>2</sup> in a section on the relation of age to fecundity, says (p. 590):

The fecundity of the average individual woman may be described, therefore, as forming a wave, which, starting from sterility, rises somewhat rapidly to its highest point, and then gradually falls again to sterility. There can be no doubt that animals as a general rule tend to follow a similar law.

<sup>1</sup> Papers from the Biological Laboratory of the Maine Agricultural Experiment Station, No. 43.

<sup>2</sup> Marshall, F. H. A., "The Physiology of Reproduction," London (Longmans, Green & Co.), 1910, pp. xvii + 706.

A record of the entire breeding history of a rather remarkable ewe, of which I made a note some time ago for another purpose, illustrates this law in so clear a manner that it seems desirable to publish it with some discussion, particularly since the place of original appearance of the record is neither readily accessible nor likely to come to the attention of the biologist.

The record referred to was contributed to the *New England Farmer*<sup>2</sup> by Mr. Chas. Mattoon, of Lenox, Mass. The ewe in question was owned by one of his neighbors, Colonel Nathan Barrett, who, at the request of Mattoon, drew up the following account:

I hereby certify that I have owned a native ewe sheep, for the space of nineteen years, lacking a few days; having retained her usual vigor for seventeen years. But in the fall of 1822, I observed for the first time, and with no small degree of interest, that she slackened her pace, and went in the rear instead of front, which she continued to do for one year. After which, having nearly lost use of her eyes, and teeth, I took her under my immediate care for the last six months, until March, 1824, when she died with old age—having given me nineteen fleeces of wool, and borne me thirty-six full-grown lambs, viz.:

	Lambs		Lambs
April, 1806	1	1815	2
1807	1	1816	2
1808	2	1817	2
Apr. 3, 1809	3	1818	2
Mar. 29, 1810	3	1819	2
Making 6 lambs in 11 months and 26 days.		1820	2
1811	3	1821	1
1812	3	1822	1
1813	3	1823	0
1814	3	1824	0
		Total	36

The general accord of this case with the law discussed by Marshall is obvious. Beginning with the minimum degree of fecundity possible (excluding absolute sterility) there is a rather rapid increase to a maximum, which is maintained for a time. This is followed by a decline in fecundity more gradual than the rise, ending finally in absolute sterility.

<sup>2</sup> Vol. III., June 3, 1825, p. 353.

The case is of especial interest in the present connection because of the fact that it is a *completed* record, carried to the natural end of life of the individual. Such completed breeding records are rare for higher animals.

It is of interest to make certain biometric computations from these data. If the age of the ewe is taken as abscissa and the number of lambs born as ordinate one can calculate by the ordinary methods the arithmetic mean point of this animal's total fecundity period, and certain other constants of interest. The only difficulty in making such calculations arises from the fact that no precise statement is made as to the age of the ewe at the time when the published lambing record begins. It is altogether reasonable to assume, however, that (a) the first lamb recorded is the first one borne by this ewe, and (b) that she was about one year old when this lamb was born. These assumptions will be made in the calculating, and further it will be assumed that the abscissal classes throughout center at even years of life.

Making these assumptions I find:

(a) That the arithmetic mean point of this ewe's effective breeding life was at 8.57 years.

(b) That the median point in her breeding career was at 8.17 years. That is, she produced one half of her offspring before that age and one half after it.

(c) That the modal breeding point<sup>4</sup> (i. e., the point of maximum fecundity per unit of time) was at 7.34 years.

Taking into account the 17 years in which some young were born I find the following constants regarding the number of lambs per birth:

Mean number of lambs per birth .	2.12 lambs.
Standard deviation in number of lambs per birth . . . . .	.76 lambs.
Coefficient of variation in number of lambs per birth . . . . .	35.78 per cent.

These are intra-individual constants based on an unusually long and completed breeding

<sup>4</sup> Calculated by the approximate relation that the distance from mean to mode is three times the distance from mean to median.

history. For comparison the following intra-racial (inter-individual) coefficients of variation for fecundity in other forms are tabled:

*Constants of Variation in Fertility and Fecundity in Various Animals*

Organism	Character	Coefficient of Variation	Authority
Poland-Chinaswine.	Size of litter	27.411	Surface <sup>5</sup>
Duroc-Jersey swine.	Size of litter	25.997	Surface <sup>5</sup>
Mouse.....	Size of litter	37.5	Weldon <sup>6</sup>
Horse.....	Fecundity <sup>7</sup>	24.771	Pearson <sup>8</sup>
Man.....	Number of children	48.41	Powys <sup>9</sup>
Domestic fowl.....	Annual egg production	34.21	Pearl and Surface <sup>10</sup>

It is plain that the individual variability in "size of litter" shown by this ewe is of the same general order of magnitude as that found in other organisms for fecundity characters.

RAYMOND PEARL

#### THE INDUCTION OF NONASTRINGENCY IN PERSIMMONS AT SUPRANORMAL PRESSURES OF CARBON DIOXIDE

In a previous issue of this periodical,<sup>1</sup> I reported the results of some experiments to determine the relation of different pressures of carbon dioxide to the rate at which persimmons are rendered non-astringent by means of that gas. Two varieties were used in those experiments, *Taber 129* and *Hyakume*, as these are understood at the Alabama Experiment Station. I had already found that

<sup>1</sup> *Biometrika*, Vol. VI., pp. 433-436, 1909.

<sup>2</sup> *Biometrika*, Vol. V., pp. 442, 1907.

<sup>3</sup> Fecundity in this case means the fraction which the actual number of offspring arising from a given number of coverings is of the possible number of offspring under the circumstances.

<sup>4</sup> *Biometrika*, Vol. I., pp. 289-292, 1902. Actually only the moments of this fecundity curve are given at the place cited. From the moments we have calculated the coefficient of variation.

<sup>5</sup> *Biometrika*, Vol. V., p. 251, 1905.

<sup>6</sup> U. S. Dept. Agr., Bur. Anim. Ind., Bull. 110, Part I., pp. 1-80, 1909.

<sup>7</sup> Lloyd, F. E., "Carbon Dioxide at High Pressure and the Artificial Ripening of Persimmons," *SCIENCE*, N. S., 34: 924-928, December 29, 1911.

under normal pressure of pure and of approximately pure carbon dioxide<sup>2</sup> these varieties occupied from six to eight days in losing astringency, the *Hyakume* being the slower to respond to treatment. Under a pressure of 15 pounds of pure carbon dioxide, the period was found to be reduced to less than 46 hours. To be more explicit, 24 hours was found to be insufficient for either variety, while at the end of 46 hours all astringency had totally disappeared. The minimum period required at this pressure was not determined at the time for lack of material. It was, however, quite evident that the time necessary to render these varieties non-astringent at normal pressure of carbon dioxide can be reduced to less than one fourth at 15 pounds. It then remained until the season just closed to determine these relations more accurately and with reference also to still higher pressures. It is upon this work that I desire to submit at this time a preliminary report.

Meanwhile the results of experiments made by Dr. H. C. Gore<sup>3</sup> on the effect of carbon dioxide at normal pressure have appeared. The varieties which he studied include *Taber 23* and *Hyakume*, so that his results are distinctly pertinent in the present connection. Gore used a metal receiver especially designed by him to meet practical requirements, and, as indicated by his controls, is doubtless as efficient for exact experimentation as a glass receiver. The experiments with *Hyakume* were done at Maccleenny, Fla., so that the fruits of this variety were not subject to the exigencies of transportation. As to these conditions, therefore, Gore's experiments may be regarded as directly comparable to my own, which also were done on the ground in metal glass and wooden receivers. Gore's *Taber 23* fruits were processed in Washington. As to the numbers of fruits used in Gore's experiments, only three of *Hyakume* were available,

<sup>2</sup> The protocols of these and the remaining experiments will be published elsewhere in full.

<sup>3</sup> Gore, H. C., "Large Scale Experiments on the Processing of Japanese Persimmons, with notes on The Preparation of Dried Persimmons," U. S. Dept. of Agri., Bur. Chem., Bull. 155, May 10, 1912.

while of *Taber 23*, 68 fruits were processed, 71 serving for control. The three *Hyakume* were treated *in vitro*; the *Taber 23* in the metal receiver.

With conditions thus similar to those of my own experiments, Gore found that under normal pressure of carbon dioxide the *Taber 23* became nonastringent in two days and the *Hyakume* in 36 hours.<sup>3</sup> Previously<sup>4</sup> these had been found to yield to treatment in three days' exposure to vapor of alcohol of 5 per cent. and 25 per cent. strength in wooden tubs, the alcohol replacing, in this experiment, the *saké* of the empirical method of the Japanese. This result of Gore's I had overlooked at the time of my previous communication, or otherwise I should have been compelled to point out a discrepancy as between Gore's data and my own obtained with alcohol vapor for which I could not at that time have suggested an explanation. The discrepancy lies in the period required to render the fruit nonastringent with either carbon dioxide or alcohol vapor. Setting aside the *Taber 23* used by Gore as different from the *Taber 129* used by me, and therefore not comparable, the *Hyakume* in Gore's experiments yielded, under similar conditions, in less than one fourth the time required in mine; and, with reference to carbon dioxide alone, Gore succeeded in processing this variety under normal pressure in 36 hours, just the time, as it eventuated this year, required for apparently the same variety under 15 pounds. I do not argue from this that any doubt is thrown on Gore's work, nor would it be just to maintain the converse. It seems entirely probable rather that he and I have been working on different kinds. I have lately found that Japanese nurserymen on this continent recognize two subvarieties (using this term<sup>5</sup> as a convenience) of *Hyakume*, the fruit of one of which becomes nonastringent while still firm and on the tree, while that of the other does so only after softening. It can scarcely be doubted that the former would ap-

pear to yield to the carbon dioxide treatment more readily than the latter. Furthermore, these physiological differences may not be confined to different races of the persimmon only, but may be highly individual, and different even in the same individual from year to year. In support of this I have to cite an important observation on the fruit of *Taber 129* growing at Auburn, Ala., on the station grounds. There are two trees, from which was obtained all the fruit for my experiments in 1911 and 1912. In 1911 the fruits from both the trees were, unless processed, uniformly highly astringent until softening was advanced. To render them nonastringent while still firm and crisp occupied 6 days, in carbon dioxide alone at normal pressure. The fruit was tested each day, and there can be no doubt of the substantial correctness of the statement. In 1912, much to the surprise of both myself and my former colleague, Dr. F. A. Wolf, who aided me in carrying out the experiments to be presently mentioned, the *Taber* fruit apparently yielded to carbon dioxide at whatever pressure used, however low, and no matter how brief the treatment. But it was soon discovered that the real fact of the case was that *all the fruit was already nonastringent on the tree*, and this was true equally of fruits which were quite green and of those which were more or less of the definitive color, from yellow to deep orange. There were, moreover, in these fruits a very large number of reddened tannin masses, so that the inner portion of the mesocarp looked quite brown. That, however, this reddening of the tannin, due to oxidation, was not the cause of nonastringency is shown by the fact that the pulp was equally nonastringent where the oxidation had not occurred at all. I had previously ventured the opinion that the apparent absence of tannin from the nonastringent varieties might be due to the oxidized condition of the tannin, since I had been informed by Mr. Geo. C. Roeding, of Fresno, Cal., that the flesh of such kinds is freely interspersed with reddened cells. It now appears more probable that the reddening of the tannin masses is consequent on the nonastringency, and is not the cause of

<sup>3</sup>Gore, H. C., "Experiments on the Processing of Persimmons to render them Nonastringent," U. S. Dept. Agri., Bur. Chem., Bull. 141, September 29, 1911.

it; is indeed rather a result of the death of the tannin idioblasts,<sup>6</sup> and can be seen to proceed *in vitro* equally well, either spontaneously, but rather slowly, or rapidly under the effect of certain acids. It seems true, therefore, that the cause of nonastringency in all the varieties, whether they are the so-called nonastringent kinds or not, is the same. I have advanced an explanation of the phenomenon elsewhere<sup>6</sup> and the present issue does not call for a restatement.

In view of the possibilities in the case, therefore, I am bound to retain faith in the significance of the experiments upon which I based the conclusion that the higher the pressure of carbon dioxide, the shorter the period required to render the fruit nonastringent, especially as repetition and extension, in 1912, of the experiments of 1911 have discovered no discordant evidence.

The experiments were done during the first two weeks of September, 1912, at Auburn, Ala. The receivers used were four in number, all alike in construction. Each consisted of a piece of four-inch gas pipe two feet long, capped at both ends. A pressure gauge was inserted laterally, while each cap carried a gas cock, thus allowing the entrance and exit of the gas and air. This apparatus was cheap and efficient, but was not altogether easy to manage. It was necessary to work in a machine shop where pipe vices and large wrenches were at hand to screw home the large cap which had to be removed in order to examine the fruit. Graphite "dope" was used to make the joints tight. Though a pressure of 90 lbs. was in one case maintained for 24 hours, it usually fell a little, due to insufficient skill in getting every joint tight. The fall was, however, slight in any case, and, in view of the relations found, can be regarded as affecting the result but negligibly.

The fruits used were *Hyakume*, as stated, and *Tane-nashi*. For a supply of the latter I am indebted to Mr. C. L. Coleman, Fair-

hope, Ala., who was kind enough to send a large basket of choice material. For the name of this variety, I rely upon general acceptance in Alabama. The fruit answers also to the current horticultural descriptions. The *Taber 129*, which had been used in the experiments of 1911, were excluded for the reasons above stated.

The condition of the fruit as regards maturity was various, ranging from complete greenness to partly orange, the intermediate shades of yellow, yellow-green and yellow-orange being represented—this in *Hyakume*. The *Tane-nashi* ranged from pale yellow to orange. It was found that the rate of becoming nonastringent was *as rapid in the green as in the more mature fruits so long as they were under the influence of the carbon dioxide*. If, however, they were insufficiently processed, and then kept exposed to the air, the subsequent changes were more rapid in the more mature fruits. Maturity then did not modify the immediate effect, and the range of condition in regard of maturity rules out error due to difference of ripeness. The fact is one, moreover, of prime theoretical importance.

In charging the receivers, a corresponding number of sets of fruits was chosen in such manner that each set contained the same range of color. The charge consisted of 8 fruits in each instance. Each fruit was selected carefully for its soundness, and no bruised or otherwise injured fruit was used, except in the case of the *Tane-nashi*, which, on account of transportation, was in some instances more or less bruised. This was, however, found to have no immediate effect on the rate of processing, though the keeping of the fruit thereafter was affected, as was true also of the other kinds.

In the several experiments<sup>7</sup> pressures ranging from normal to 90 lbs., were employed, together with controls in air. By charging

<sup>6</sup> Lloyd, F. E., "The Behavior of Tannin in Persimmons with some Notes on Ripening," *Plant World*, 14: 1-14, January 1, 1911.

<sup>7</sup> Lloyd, l. c., note 5.

<sup>7</sup> While the results obtained with *Tane-nashi* are in general accord with those from *Hyakume*, they are not by any means as clear-cut and unequivocal. I shall therefore withhold them from the present discussion, but will embody them in a later account.

the receivers at different pressures and opening them at stated intervals, the period required for processing could be determined with all necessary accuracy, certainly within a very few hours. Both time and circumstance prevented a high amplitude of experimentation, so that pressures between 15, 25, 45, 75 and 90 lbs. were not tried. Concerning the highest of these (90 lbs.) it may be stated summarily that the fruit was killed, and on being taken out, at the expiration of 24 hours, was discolored (brown) and watery. It was, however, nonastringent. Whether the cause of death was due to rupture of the cells consequent on the too rapid increase or decrease of pressure, or on asphyxiation accompanied by change in permeability of the protoplast, I can not say. If the fruit was too soft, and the pressure released too rapidly, even when the initial pressure was no higher than 15 lbs., the fruit was burst, and microscopic examination showed that many individual cells were also in the same case.

The experiments were, moreover, designed to determine (1) the minimum period of time required to cause nonastringency at the pressures used; and (2) the after-effect of dosage at given pressures applied for periods insufficient in themselves to produce nonastringency. Aside from the theoretical interest attaching to the latter question, the possible economic application of short dosage, if followed by nonastringency within definite periods, was contemplated. The minimum period required to effect nonastringency was determined critically for normal, 15 and 45 lbs. pressure, the volumes of  $\text{CO}_2$  being 1, 2 and 4, respectively. The after-effect of dosage at 45 and 75 lbs. was determined with sufficient accuracy to indicate definite quantitative relations.

It was found, in the first place, that at the end of 36 hours with 15 lbs. pressure (experiment 12 *a-d*, 1912) the fruits were nearly nonastringent. Further treatment for three hours produced complete astringency. It is probable that the period required is nearer 36 than 39 hours, but not less than the former nor more than the latter. At 45 lbs. 12 hours was found insufficient (experiment 11 *d*, 1912),

while at the close of 15 hours there was a scarcely perceptible astringency (experiment 9, 1912). It may be recalled that the variety in question (*Hyakume*, an "astringent variety") had been found in 1911 to require 6-7 days at normal pressure, and less than 46 hours at 15 lbs. Controls in air this year remained hard and astringent during the whole period of experimentation, nearly three weeks. It therefore emerges that, as I have previously maintained, there is a quantitative relation between the amount of  $\text{CO}_2$  available and the rate at which the astringency disappears. Green fruits yielded as readily to both pressures as yellow or pale orange, which appears to indicate that, during the natural course of events, after the fruit has its full growth at any rate, the tannin cells are ready for the change leading to nonastringency, and that this change is induced by some condition set up in the tissue external to the tannin cells themselves. The graph determined by the data above indicated is that of a rectangular hyperbola, and this may be held tentatively as expressing the relation of time and pressure to the disappearance of astringency.

In the second place, the fact was established that nonastringency ensues the more rapidly, the longer the exposure to  $\text{CO}_2$ , though this in itself is not sufficient to bring about the result. Pressures of 45 and 75 lbs. were used, the treatments being for 3, 6, 9 and 12 hours. After a pressure of 45 lbs. applied for 3 hours, nonastringency ensued in from 71 hours (for orange-colored fruits) to 192 hours (for yellow and green fruits). After 6 and 9 hours exposure, 45 hours were required, the evidence being that the period was somewhat less for the longer exposure. After 12 hours, the fruit became nonastringent in something over 18 hours. After 75 lbs. pressure, nonastringency was effected in a somewhat shorter period, but in view of the possible significance of the quantitative relations indicated above, but little difference should be expected between the results caused by 45 and 75 lbs. After 3 hours exposure, nonastringency followed in 62 to 185 hours; after 6 hours in something over 34 hours, after 9 hours less

than 34 hours, and after 12 hours in about 20 hours. In the receiver charged for 12 hours, however, the pressure fell from 75 to 50 lbs., so that no difference worthy of note may be seen as between this and the corresponding experiment for 45 lbs. The difference in effect of the 6 and 9 hour exposures was very small with both 45 and 75 lbs. pressure, a fact which I am unable to elucidate. Aside from this, the period required for becoming nonastringent was, roughly speaking, in inverse ratio to the time of exposure to the gas. It will be readily understood by those who have worked with such objects as ripening fruits that it is often difficult to fix upon a suitable indicator of the final limit of any of the physiological processes involved. Thus, in these experiments just described, the difference in rate of change in green and orange-colored fruits makes it difficult to decide on what is to be regarded as the final point at which nonastringency ensues. Furthermore, there is the more variation between different fruits the longer the period of ripening, and the end point is correspondingly difficult to fix.

I have, therefore, endeavored to apply a test different from that of tasting, at least for purposes of control. The mucous membranes are of course extremely sensitive; nevertheless, it becomes difficult, as the end point is approached, to judge clearly. It is furthermore of the highest importance to examine the physical characters of the tannin-mass, which has been shown to be a colloidal complex<sup>8</sup> in order to determine whether the condition reached by it when nonastringency has been accomplished quickly is identical with that reached after a slow process. A former study of the reaction of alkaloids<sup>9</sup> with the tannin-mass showed me that as nonastringency is approached, the coarsely granular precipitate gives way to an increasingly finer one, so that an ultramicroscopic and eventually an amicroscopic suspensoidal condition is reached. The only change obvious on applying the reagent then becomes one of color,

<sup>8</sup> Lloyd, F. E., "The Tannin-colloid Complexes in the Fruit of the Persimmon," *Biochemical Bulletin*, 1: 7, September, 1911.

the tannin-mass becoming brown, lighter brown, darker and paler yellow as the definitive state is approached. By reflected light the changes are evident as a decreasing milkiness.<sup>9</sup> By correlating these progressive changes with the disappearance of astringency, it has become evident that it is quite possible to decide whether a fruit is astringent or not without tasting it. This is because the physical condition of the tannin-mass is the same on the arrival of nonastringency, whether this has been accomplished in 15 hours or as many days.

There remains one further point of which to speak. When one uses such an expression as "the period required to become nonastringent," an incorrect notion may be implied. It is not to infer that in one case the process itself is slow and in another rapid (though this may be the case), but that the time required to start the process may differ. It remains to determine the actual fact, and this is necessary to an understanding of the whole matter.

*Note.*—The work, of which the above is a partial account, was done at the Alabama Agricultural Experiment Station as an Adams Fund Project. I have to thank Dr. F. A. Wolf for hearty and arduous cooperation in carrying on the experiments.

FRANCIS E. LLOYD

MCGILL UNIVERSITY

#### THE AMERICAN PHYSIOLOGICAL SOCIETY

THE society held its twenty-fifth annual meeting in Cleveland, Ohio, December 29, 1912, to January 1, 1913. Sixty-nine members were in attendance. Two executive sessions and six scientific sessions were held, two of the latter being joint sessions, one each with the American Society of Biological Chemists and Section K of the American Association for the Advancement of Science. The joint session with the American Society of Biological Chemists was opened with exercises in memory of the late Waldemar Koeh. After the

<sup>9</sup> These changes are analogous to those seen first by Loew and others, and recently described in detail by Czapek. Czapek, F., "Ueber Fällungsreactionen in lebenden Pflanzenzellen und einige Anwendung derselben," *Ber. deut. bot. Ges.*, 38: 147-159, 1910.

members of the society had arisen as a token of respect to the memory of Dr. Koch, Dr. A. P. Mathews delivered the memorial address.

The following papers and demonstrations, forty-seven in all, were read and discussed:

S. Simpson: "The Rate of Growth in the Dog."

G. N. Stewart: "Further Observations on the Blood-flow in Man."

J. A. E. Eyster and W. J. Meek: "Experiments on the Sinus Region of the Mammalian Heart."

G. C. Robinson (by invitation) and J. A. Auer: "Cardiac Anaphylaxis as Shown by the String Galvanometer."

W. T. Porter: "The Functional Relations of Cells in Nerve Centers."

R. S. Lillie: "Correlation between the Anti-stimulating Action and the Anti-cytolytic Action of Anesthetics."

E. B. Meigs: "Studies in the General Physiology of Smooth Muscle."

W. P. Lombard: "The Tickle Sense."

O. Folin, W. B. Cannon and W. Denis (by invitation): "A New Colorimetric Method for the Determination of Epinephrin."

J. Auer and S. J. Meltzer: "The Splanchnic as a Depressor Nerve."

F. R. Miller: "The Salivary Secretion Centers in the Medulla."

W. T. Porter: "A New Electrical Clock."

S. P. Beebe: "A New Form of Apparatus for Artificial Respiration."

A. D. Hirschfelder: "Some New Apparatus."

L. Loeb: "The Influence of Pregnancy on the Cyclic Changes in the Uterus."

G. Lusk: "Metabolism of a Dwarf."

H. S. Gasser (by invitation) and A. S. Loevenhart: "The Mechanism of Stimulation by Oxygen Want."

T. B. Osborne and L. B. Mendel: "Feeding Experiments Relating to the Nutritive Value of the Proteins of Maize."

A. J. Ringer: "The Fate of Fatty Acids in Diabetic Organisms."

A. B. Macallum and W. R. Campbell: "On the Secretion of Pure Acid by the Kidney" (with demonstration).

D. Marine: "Hypertrophy and Hyperplasia of the Parathyroid in Birds."

G. H. Whipple: "Hematomogenous Jaundice and its Relation to the Liver."

E. V. McCollum: "The Influence of the Plane of Protein Intake on Nitrogen Retention in the Pig."

R. S. Hoskins: "Relation of Fatigue Metabolites to Epinephrin Efficiency."

D. R. Hooker: "Perfusion of the Respiratory Center in Frogs; the Influence of Calcium and Potassium on the Respiratory Rhythm."

A. Hunter: "The Nitrogen Excretion of Normal and of Thyroidectomized Sheep."

A. L. Tatum (by invitation): "Studies in Experimental Cretinism with Suggestions as to a Biological Test for Thyroid Secretion."

R. A. Gesell (by invitation): "The Relation of Pulse Pressure to Renal Secretion."

C. Brooks and A. B. Luckhardt: "The Arterial Blood Pressure during Vomiting."

T. Sollmann and J. D. Pilcher (by invitation): "The Effects of Aortic Compression on the Circulation."

E. G. Grey (by invitation) and A. D. Hirschfelder: "Clinical Observations upon the Carbon Dioxide Percentage of Alveolar Air."

C. W. Greene and W. Y. Skaer (by invitation): "On the Fat Contents of the Mammalian Gastric Glands in Relation to the Stages of Digestion."

S. Tashiro (by invitation): "The Chemical Change in Nervous Tissue during Excitation."

I. F. Zucker (by invitation): "The Pressor Property of Shed Blood."

H. Cushing, L. H. Weed (by invitation) and C. Jacobsen: "Further Studies on the Role of the Pituitary Gland in Carbohydrate Metabolism, with Special Reference to the Autonomic Control of the Posterior Lobe Secretion."

S. A. Matthews and D. D. Lewis (by invitation): "The Pars Intermedia; Its Place in Diabetes Insipidus."

Lydia M. Degner (by invitation) and A. E. Livingston (by invitation): "Effects of Thyroidectomy and Castration, respectively, on the Pituitary in the Rabbit."

P. W. Cobb and L. R. Geisler (by invitation): "The Influence on Foveal Vision of the Brightness of Surroundings."

D. E. Jackson: "Some Observations on the Peripheral Action of certain Drugs."

G. L. Kite (by invitation): "The Relative Permeability of the Surface and the Interior Portions of the Cytoplasm of Animal and Plant Cells."

J. D. Pilcher (by invitation): "The Excretion of Nitrogen Subsequent to Ligation of Successive Branches of the Renal Arteries."

W. E. Burge: "The Uniform Rate of Destruc-

and Surgeons; H. G. Barbour, Yale Medical School; W. B. MacNider, University of North Carolina; A. R. Moore, University of California; H. B. Williams, Columbia University; V. H. K. Moorhouse, Washington University.

G. H. Whipple: "Intestinal Obstruction; Study of a Toxic Substance Present in the Intestinal Mucosa."

S. J. Meltzer: "Is the Pulsation of the Anterior Lymph Hearts Responsible for the Action of some Drugs in Cardiotomized Frogs?"

H. McGuigan: "The Synergic Action of Morphine and Strychnine."

Symposium: "Some Recent Applications of Physical Chemistry in Biology."

(a) A. B. Macallum: "Surface Tension."

(b) L. J. Henderson: "The Control of Neutrality in the Animal Body."

The following eleven papers were read by title: C. D. Snyder: "The Influence of Temperature on the Mammalian Heart."

M. Dresbach (by invitation): "A Bloodless Method of Recording Blood Pressure in Animals."

A. J. Carlson: "Some Observations on the Physiology of the Empty Stomach and Esophagus in Man and Dog."

H. C. Bradley: "The Problem of Enzyme Synthesis."

G. W. Crile: "The Relation between the Physical State of the Brain Cells and Brain Functions—Experimental and Clinical."

Y. Henderson and C. T. Flynn (by invitation): "Oligemia in Acute Disease."

H. McGuigan: "The Secondary Depression by Epinephrin; the Rate of Destruction of the Pressor and the Hyperglycemia Actions of Epinephrin."

W. B. Wherry (by invitation): "On the Transformation of Amebæ into Flagellates and Vice Versa."

P. E. Howe (by invitation) and P. B. Hawk: "The Influence of Fasting on the Creatine Content of Muscle."

C. D. Snyder: "A Study of the Electromyograms."

A. J. Carlson: "The Correlation of the Physiological States of the Thyroid of the Fetus and of the Mother."

The following persons were elected to membership in the society: G. C. Robinson, Rockefeller Institute; J. D. Pilcher, P. J. Hanzlik, R. S. Pearce, Western Reserve Medical School; G. C. Schneider, Colorado College; A. H. Ryan, University of Pittsburgh; M. Dresbach, Cornell University; G. Bachmann, Atlanta College of Physicians

School; W. B. MacNider, University of North Carolina; A. R. Moore, University of California; H. B. Williams, Columbia University; V. H. K. Moorhouse, Washington University.

At this meeting considerable progress was made toward the formation of a close federation of the American Physiological Society, the American Society of Biological Chemists and the American Society for Pharmacology and Experimental Therapeutics. The society expressed its desire to enter into such a federation, and a committee was appointed to confer with similar committees of the sister societies with a view to bringing it about. The committee was granted power to make the arrangements for the next annual meeting. This committee was also directed to confer with a similar committee of the American Society of Naturalists to consider the advisability of establishing closer relations with that society.

With regard to the measures of remedying the threatening congestion of programs that were referred to the council at the last annual meeting, it was decided that should the federation of the three societies be accomplished, the secretaries of the federated societies be empowered to attempt the equalization of the programs of the three societies by placing papers on the program of the society to which its subject is most closely related. It was also decided to place at the end of the program papers presented by non-members, and in the event of congestion of the program, to read these by title.

The following officers were elected for the year 1913:

*President*—S. J. Meltzer, New York.

*Secretary*—A. J. Carlson, Chicago.

*Treasurer*—Joseph Erlanger, St. Louis.

*Additional Members of the Council*—W. B. Cannon, Boston; F. S. Lee, New York.

The following members of the society were appointed by the president to form the editorial committee on the publication of the *American Journal of Physiology* for 1913: A. T. Porter, A. J. Carlson, Joseph Erlanger, W. H. Howell, F. S. Lee, Graham Lusk, S. J. Meltzer.

The local committee on entertainment, following the plan that was first tried last year at Baltimore by the members and friends of the society, again agreed to dispense with all private entertainment, and to substitute for it informal subscription dinners followed by smokers each evening while the society was in session. These functions were open to all members and guests of the societies of the experimental biological sciences. It was again

demonstrated that this method of entertainment, by bringing all of the members together under conditions permitting of informal discussion and exchange of ideas, adds greatly to the pleasure and value of the meeting.

JOSEPH ERLANGER,  
*Acting Secretary*

WASHINGTON UNIVERSITY MEDICAL SCHOOL

### THE ASSOCIATION OF AMERICAN GEOGRAPHERS

THE Association of American Geographers held its ninth annual meeting at New Haven, Connecticut, December 27-28, 1912. The sessions were held in Lamson Hall, Yale University, and an informal meeting took place Friday evening at the Graduates' Club. In the absence of the president (Professor Salisbury), Mr. M. R. Campbell, the first vice-president, presided. About thirty members attended.

It is gratifying to the members to see the increasing number of papers on anthropogeography, regional geography, and climatology that deal with human relations, a feature less prominent in the earlier programs of the association. Seven purely physiographic papers were presented out of a total of sixteen. Great interest is manifested in the *Annals* of the association since the appearance of the first volume during the past year. The publication committee has performed a distinct service to geographic science in securing papers of high quality and a volume of excellent appearance.

The newly-elected officers for 1913 are as follows:

*President*—Henry G. Bryant.  
*First Vice-president*—Ellsworth Huntington.  
*Second Vice-president*—Charles C. Adams.  
*Secretary*—A. P. Brigham.  
*Treasurer*—F. E. Matthes.  
*Councillor* (for three years)—R. DeC. Ward.

The publication committee appointed for two years (1913 and 1914) consists of R. E. Dodge, editor, and Alfred H. Brooks, H. E. Gregory and H. H. Barrows.

ISAIAH BOWMAN,  
*Acting Secretary, Session  
of December, 1912*

### THE CONVENTION OF THE AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS

THE sixth annual convention of the American Society of Agricultural Engineers was held at the Great Northern Hotel, Chicago, December 26, 27

and 28. The attendance of members was very good, but the noticeable feature this year was the unusually large number present of manufacturers, designers, etc. This is very encouraging to the officers and shows that the work of the society is being kept practical enough to interest the commercial man.

Thursday afternoon was devoted largely to general agricultural machinery interests. Mr. Sjogren, of the University of Nebraska, presented a paper on "Tests of Corn Planters," which gave the results of a series of tests run on accuracy of drop. Professor C. A. Ocock, of the University of Wisconsin, in his paper on "Draft of the Plow," showed by tables and curves, the variations in the draft of a plow as affected by width, depth, type of moldboard and condition of soil. In the paper on "Isolated Gas-lighting Plants" Mr. Eugene Becker, of the Atlantic Blau-Gas Company, described the different systems using gasoline gas, acetylene and Blaugas, with the advantages and disadvantages of each. Admixture of a certain proportion of air made either of these gases explosive, either a richer or leaner mixture being non-explosive: gasoline—2 per cent. to 5 per cent. by volume of gasoline vapor—98 per cent. to 95 per cent. air; acetylene—2 per cent. to 49 per cent. by volume acetylene—98 per cent. to 51 per cent. air; Blaugas—4 per cent. to 8 per cent. by volume Blaugas—96 per cent. to 92 per cent. air. Thus acetylene has a very wide explosive range, Blaugas next, and gasoline least. On the point of quality of light, acetylene is the best, but for convenience and safety Blaugas was probably most satisfactory.

Friday was devoted to the tractor and standardization questions. In his paper on "Testing of Gas Tractors" L. W. Chase, of the University of Nebraska, reviewed the results secured through the Winnipeg Motor Contests. C. F. Hirschfeld, of Cornell University, in a paper on "Principles of Fuel Oil Engines" explained the matter of carburetion of various fuel oils, the principles and chemistry of their combustion and the difficulties met in adapting them as fuels for internal combustion engines. E. H. Ehrman, of the Chicago Screw Company, in his paper on "The Standardization Work of the Society of Automobile Engineers," gave the society an account of the methods and guiding principles for the standardization work of his society. The influence of standardization in cheapening production and repairs and in keeping down monopoly was brought out in

"Standardization in Agricultural Engineering" by J. B. Davidson, of Iowa State College. This subject was continued by "Standards in Agricultural Machinery," by J. A. King, of Sears, Roebuck and Company. W. J. Brandon, of the Avery Company, in his paper, "Standards in Gas Tractor Construction," took up the question of standardization as applied to the gas tractor industry.

Saturday was set aside for papers along the teaching phase of the work. A paper by Daniels Scoates, of the Mississippi Agricultural College, on "Laboratory Exercises in Farm Machinery," brought out the fact that the subject naturally divides into farm mechanics, farm motors and farm machinery. "The Design of an Agricultural Engineering Building," by H. C. Pamsower, took up the design of a proposed building for the Ohio State University. The plans as shown were discussed by E. A. White, of the University of Illinois, and J. L. Mowry, of the University of Wisconsin.

The committee on the proposed Bureau of Agricultural Engineering reported through J. B. Davidson that the society should lend all possible aid towards securing the passage of the Rainey bill in its present form, providing the creation of a Bureau of Farm Power, inasmuch as parts of the work proposed to be included in the wider plan is already partly taken care of under different bureaus and there would be great opposition towards making the necessary reorganizations.

Extensive changes were authorized in the constitution of the society, especially as to classes of members, qualifications of members, methods of electing members, and in dues. The intention is to make the requirements for active membership more rigid, but to provide a wider range of membership through associates, juniors and affiliates. Originally composed of college men engaged in the teaching of agricultural engineering subjects, the society has been broadened to include manufacturers, technical men, etc. The increase in membership has been rapid, that of the present year being between forty and fifty per cent.; while under the new provisions of the constitution, and due to the increased interest aroused by the standardization and tractor contest problems, a still greater increase is looked for in the present year.

The following officers were elected for the ensuing year:

*President*—L. W. Chase, Lincoln, Neb.

*First Vice-president*—E. A. Rumely, La Porte, Ind.

*Second Vice-president*—J. A. King, Chicago, Ill.

*Secretary*—I. W. Dickerson, Urbana, Ill.

*Treasurer*—J. L. Mowry, St. Paul, Minn.

*Councilor*—J. B. Davidson, Ames, Ia.

I. W. DICKERSON,

*Secretary*

## SOCIETIES AND ACADEMIES

### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 464th regular meeting of the society was held at 4:30 P.M., December 17, 1912, in Room 43 of the New National Museum, the president, Mr. Stetson, in the chair.

Professor C. V. Piper read a paper on the Filipinos and the problem of their government, beginning by a general résumé of the insular conditions and various peoples dwelling there, of whom he said the Negroes, now found mainly in four islands but once in nearly all, are generally regarded as the original inhabitants, the Igorrotes and other wild tribes being the next to arrive, the Filipinos next, perhaps about A.D. 500, and the Moros last, not long before the time of the Spanish occupation. At some length he described the Filipino characteristics, distinguishing between the small educated minority and the majority of ignorant laborers. His conclusion was that immediate independence would be injurious, but that our government should establish some limit in the future defined by conditions of education of the majority of the race. The most remarkable thing we are doing there, he said, is the attempt, for the first time in history, to educate an inferior people *en masse*. The Asiatic European colonies have little faith in its success, but are influenced by it and our general policy.

Dr. Riley B. Moore read a paper on his observations in St. Lawrence Island, one hundred by thirty miles of treeless swamp and tundra, inhabited by some two hundred and fifty people, the debris of five different tribes in the Bering Sea. Some of these resemble Sioux Indians: others are typical Mongolians, with all intervening kinds. In summer they have a profusion of birds and fish to feed on; but in other seasons their food is whale-meat, seal-meat and walrus-meat. They live with little ventilation and many skin diseases. Tuberculosis also is very common. The death rate has long exceeded the birth rate.

W. H. BABCOCK

## INTRODUCTION

THE primacy of New York among the states in population, wealth, manufacture and commerce is based on its physical characters—geologic structure, physiographic relief and geographic relations. The state has the greatest range and perfection in its stratigraphic series and the greatest variety in physiographic features. In scenery other states may possess single features of surpassing grandeur and beauty, like the Colorado Grand Canyon, Yosemite Valley, Crater Lake, the mountains of the Cordillera or the snow-capped volcanic cones of the northwest, but for abundance and variety of beautiful scenery of educational value New York may claim first place. In the variety and excellence of Pleistocene phenomena the state probably excels any other equal area of the earth's surface. This is due to the varied and unusual physiography combined with a favoring attitude of the area in relation to the continental glacier. The features of special excellence occur largely in the western part of the state. These are the series of more than twenty parallel, north-sloping valleys which hold the unique series of twelve so-called Finger lakes; the remarkable succession of glacial lakes in the Ontario drainage area; the conspicuous, abandoned channels of the rivers that drained those lakes; the surpassing display of drumlins, of kames and eskers; the fine series of mo-

<sup>1</sup> Annual address of the president of the Geological Society of America, read on December 28, 1912. The numerous maps which illustrated this address are here omitted.

raines, and the large number of Postglacial ravines.

The purpose of this writing is to utilize this remarkable display of Pleistocene phenomena in illustration of the glacial history and in brief discussion of some problems in the philosophy of glaciation.

#### MULTIPLE GLACIATION

The accepted facts of multiple glaciation in the Mississippi basin coupled with proofs of Prewisconsin drift in Pennsylvania and New Jersey and on Long Island, with accumulating evidences in New England, demands the theoretical acceptance of at least dual glaciation for New York state. But the positive proof, in the field, of a Prewisconsin ice sheet has not been found. In several localities the deeper till is so unlike the upper till that it strongly suggests a separate origin. Some singular topographic features are not satisfactorily explained without appeal to the earlier ice invasions. The Rutland Hollow, east of Watertown, is an example. Many erosion features, especially in the St. Lawrence district, seem inconsonant with the work of the latest ice.<sup>2</sup> However, we have found no example of interglacial or warm-climate deposits interbedded in the till. Such should be expected and sought, but at present we can only say that multiple glaciation in New York, at least north of Long Island, is quite certain in our philosophy but that it remains unproven in observation.

Although our glacial phenomena in New York are doubtless not the effects of merely the latest or Laurentian ice sheet, the latter so strongly dominates that for purpose of this writing it is impracticable to attempt discrimination, and unless specially noted it will be understood that reference is to the latest, or Wisconsin, glaciation.

<sup>2</sup>For discussion of this subject see N. Y. State Museum Bulletins, No. 145, pp. 164-172; No. 160, pp. 17-18.

#### LAURENTIAN (LABRADORIAN) ICE BODY

The reach or extent of the latest ice sheet has long been known in a general way through the early work of Upham, Lewis and Wright in tracing the terminal moraine. In later years the stretches of the terminal moraine which lie in New York have been reexamined, on Long Island by Woodworth and Fuller and Veatch, and in Cattaraugus county by Leverett. There are two small areas in the state which the ice sheet did not cover, the south side of Long Island and the district partly enclosed by the northward bend of the Alleghany River.

At its maximum the ice sheet covered the highest points in the state, the Adirondack (5,344 feet) and the Catskill (4,205 feet) mountains. Judging from the Antarctic and Greenland ice caps the surface of the Laurentian shield was a low dome of fairly uniform curvature, uninfluenced by the irregularities of the submerged land surface. Our only means of estimating the thickness of the ice cap is by assuming a gradient of the surface slope, as suggested by observations on the existing polar ice fields. Such data, however, can be safely used only in a suggestive way when applied to the Laurentian ice shield, because the difference in latitude must be an important factor. The border of our ice field, in latitude 41 to 44 degrees, was subjected to so much greater solar radiation and consequent higher temperatures, with heavy precipitation and rains, that it must have had increased plasticity and resultant mobility, giving the surface slope diminished gradient. But on the other hand the snow supply over the central area or alimentation ground of the ice field must have been greater than over the polar fields, which might give greater depth and steeper gradients toward the interior of the field. The anticyclonic winds over the ice cap, re-

cently emphasized by Hobbs, would brush the snow toward the borders of the field and so tend to reduce the surface slope of the interior.

Shackelton found that the great outlet glacier in Antarctica, named the Beardmore, had a rise of 80 feet per mile for 100 miles, with declining rate inland, attaining about 11,000 feet in 275 miles, or 40 feet per mile for the entire distance. If we assume a slope of 60 feet per mile for the glacier surface over western New York it gives an altitude of over 9,000 feet on the area of Lake Ontario, the margin of the ice sheet lying at near 2,000 feet altitude. Over central New York (district of Oneida Lake) the altitude would be about the same; and if to this we add 30 feet per mile to the middle of the Adirondacks it gives 3,000 feet more, or over 12,000 feet altitude. If we assume 40 feet per mile on the Hudson-Champlain meridian it gives 12,500 feet of ice on the Canadian boundary. Thirty feet per mile gives over 9,000 feet of ice. These figures may be somewhat excessive, but they at least prove the fact of a great thickness of solid water piled over the state. The effect of such weight will be noted later.

The ice mass had a spreading or radial flow, as a plastic body, due to its own weight. The prevailing direction over New York was southwestward, except that in the lower Hudson Valley the flow was southward, conforming to the valley. The waning or thinning ice sheet was deflected by the larger topographic relief, and when the ice mass resting over the Ontario basin ceased to be impelled by thrust from the northeast it developed a spreading flow, radiating from the area now occupied by Lake Ontario. This is well shown by the orientation of the drumlins in the Ontario basin. A good illustration of valley diversion is shown in the maps, depicting how

the Hudson lobe and the Ontario lobe pushed into the Mohawk Valley from opposite directions, impounding glacial waters between them. As the direction of flow near the margin of the ice sheet must incline to right angle, or normal to the ice front, the direction of latest movement in any district can be approximately known if the ice limit is determined. The series of maps accompanying this writing show several stages in the waning and disappearance of the ice and suggest the direction of flow at different positions.

The set of maps gives fifteen positions of the ice front during its recession across the state. A larger number could be depicted, but only those have been selected which have some significance in the lake and drainage history. The criteria used in locating the ice front positions are the moraines and the ice-border river channels, the latter correlating with lake levels and shore features.

The recession of the ice front was certainly not steady or continuous, but must have had considerable oscillation, readvances and reretracts. The heavier belts of moraine and the lines of long-lived ice-border drainage probably represent readvanced positions.

The length of time represented by the passage of the ice front across New York is unknown, but is certainly scores of thousands of years. Probably 100,000 years is not too long. We may not judge the rate of waning by the present behavior of the ice fronts in Greenland and Antarctica, as the climatic factors due to difference of latitude must have been effective. If the oscillations of the ice front were due to any irregular or nonperiodic variations of climate, then we can have no idea of the time involved either in the advance or the waning of the ice sheet. And the only periodicity in climatic factors now recognized

that seems adequate is the precession of the equinoxes, having a variable but average period of about 21,000 years. Taylor has studied the Cincinnati-Mackinac moraine series from this viewpoint, and concludes that the fifteen rather equally spaced moraines represent 75,000 to 150,000 years, using the minimum length of the precession period.<sup>3</sup> The eight or ten morainic belts which we now recognize in western New York may correlate with that many on the Cincinnati-Mackinac meridian, but the recession of the ice front on the Hudson-Champlain meridian probably represents a much longer time than the Ohio-Michigan series.

If the changes in geologic climates be due to variation in solar radiation it is conceivable that some minor secularity might be responsible for the oscillations of the ice front. Variation in the amount of carbon dioxide content of the atmosphere can more reasonably be invoked to explain the larger and more irregular changes in ancient climates than for the shorter and more regular changes that caused the ice front oscillations. The same is true of continental elevation as a cause of colder climate.

#### GEOLOGIC EFFECTS OF THE ICE SHEET

*Erosional work.*—The subject relating to glaciers that has been the cause of the greatest difference of opinion is the erosive power or destructional work. The writer will here not discuss seriously glacial erosion in general, but only so far as it applies to New York.<sup>4</sup>

That mountain glaciers abrade their valleys and by moderate erosional work change the V-shape to the U-shape has long been apparent. The destructive work at the head of the glacier in production of cirques is fully recognized, although this is

largely atmospheric effect. All argument for deep erosion by glaciers based on the abrasional or plucking action of mountain or stream glaciers fails when applied to New York, as there were no effective mountain glaciers in New England and New York, at least not during the waning of the Laurentian ice body. The ice disappeared from the more elevated tracts, while lingering in the lowlands. Whatever the erosive power attributed to mountain glaciers of Norway or New Zealand, it can not be invoked here, as New York had no such glaciers. We have to consider only the work of a continental glacier. Whatever destructive effects an ice cap may have under its central or subcentral mass, it has long been admitted that it is not a vigorous erosive agent in its border zone or dissipating belt. The district in New York, the Finger Lake area, which has been used in illustration of glacial valley erosion, was always in merely the outer zone, or that of predominant deposition by the Laurentian glacier. All students of New York geology practically agree on the lack of vigorous ice erosion over all the rest of the state. Those who have worked in the Adirondacks and in the Champlain and St. Lawrence valleys have noted the proofs of a weak erosion.<sup>5</sup> It has been shown by Gilbert and the writer that erosion was weak on the Ontario lowland of western New York. The claim for deep erosion has been only for the valleys of the Finger lakes, specially Cayuga and Seneca, the claim based chiefly on anomalous topographic features.

The advocates of glacial deepening of the valleys appeal either to vigorous currents at the bottom of the ice sheet or to the tongue-like lobations of the ice front, to deeply gouge the bottoms of the valleys so as to produce hanging side valleys and

<sup>3</sup> *Journal of Geology*, Vol. 5, pp. 421-465, 1897.

<sup>4</sup> For the argument in general see *Bull. Geol. Soc. Am.*, Vol. 16, pp. 13-74, 1905.

<sup>5</sup> See N. Y. State Museum Bull. 145, pp. 147, 171-172, 1910.

"oversteepening" of the lower slopes of the main valleys. The existence of effective basal currents in the region under consideration seems highly improbable. The general land slope was opposed to the ice flow, that is, the ice was moving on an upslope. The lower or basal ice was very heavily burdened with rock rubbish and would naturally serve as the bridge over which the upper ice traveled, partly by shearing and partly by superior plasticity. But if for argument we grant the existence of effective bottom currents, then we are forced to concede that under the conditions of great vertical pressure, with the movement on an up-slope in soft shale rocks, the erosion would have to be by abrasion and not by plucking. At its intensest, abrasion must be a slow and a self-checking process. Long ago Russell emphasized the fact that plasticity of the ice is reduced in proportion to its burden of drift. Admitting this, it follows that an excess of rock stuff in the basal ice, the inevitable result of heavy erosion, would produce stagnation. Moreover, the excessive product of grinding would serve as a buffer to protect the bed rock, just as a stream full-loaded with detritus ceases to erode.

If the lobations or valley tongues of the ice margin had any erosive effect comparable to mountain glaciers, such work should have been greatest south of the land divide, or where gravity directly assisted the flow. But the conspicuous lack of erosive work on the uplands and south of the divide is frankly admitted. In description of the area covering the eight quadrangles of the Watkins-Ithaca-Elmira-Owego district, in the U. S. Geological Survey Folio 169, Professor Tarr, who was the leading advocate of glacial erosion of the Finger Lake valleys, wrote:

In harmony with this evidence of slight erosion is the fact that the mature upland divide areas

have suffered notable modification only by deposition and not at all, so far as can be seen, by ice erosion (page 16).

In the southern half of the area glacial erosion was not sufficient to remove the products of preglacial decay from the hills, nor, so far as any evidence goes to show, to modify perceptibly the topography even of the valleys (page 31).

North of the divide the lobations of the ice front were pushed up the valleys by the pressure of the ice in their rear, and were so heavily loaded with drift that they were not eroding, but depositing. The fact of superload of drift is clearly shown by Tarr's map of the surficial geology. South of the divide morainal drift is almost entirely lacking in the south-leading valleys and only scantily represented in the larger east and west Susquehanna and Chemung valleys. Tarr says:

On the upland, south of the area of the recessional moraines, little moraine material is found and no definite system has been worked out.

The complex of moraines in the northern part of the Watkins Glen quadrangle and the northwestern part of the Catatunk quadrangle, contrasted with the general absence of moraines in the southern half of the area, forms one of the most striking features of the Quaternary geology (page 17).

The heavy morainal drift in the valleys north of the divide was not derived from erosion of those valleys, but was the accumulated rock rubbish acquired by the lower part of the ice sheet during its entire journey across the state. When the ice was thick enough to override the divide and flow south it was the superficial, drift-free ice that passed across, while the lower, drift-loaded and relatively stagnant ice reposed in the Ontario basin and its valleys, serving as the bridge that was overridden by the clearer and more plastic superficial layers. In evidence of this is the relative absence of drift south of the divide, and the almost entire absence of crystalline rocks or far-traveled material. Quoting Tarr:

In the uplands south of the recessional moraines foreign fragments are much more rare, and in some parts of the uplands a careful search is required to find even a small pebble of crystalline rock, while boulders are practically absent (page 16).

To whatever extent the ice in the margin of the snow field was produced by the centrifugal, anticyclonic winds from the interior of the ice cap, as suggested by Hobbs from study of the existing continental glaciers,<sup>6</sup> it also favored lack of drift in the periphery of the ice body. With the waning and thinning of the ice cap the drift-loaded lower ice was finally uncovered so as to constitute the marginal belt, and was then subjected to thrust or push from the thicker body on the north. At this stage the heavy moraine deposits were made in the valleys, producing the present drainage divide, and the lobations of the ice front built the crescentic lateral-terminal ridges north of the divide. At a later stage of the waning, when the required factors were properly combined and balanced, the drumlins were constructed on the lowlands, northward.

Many facts are cited by Tarr showing the impotency of the latest ice sheet, and he finally admitted that the

Wisconsin ice sheet failed to notably modify the topography in the greater part of this area (page 16).

This would seem to terminate the debate about glacial erosion in the Finger Lake district. But it does not, as the responsibility for the anomalous topography is shifted back to the Prewisconsin glaciers.

This carries with it the necessity of believing in 1,500 feet of vertical erosion in the Seneca Valley by the continued ice work of at least two periods of glacial occupation, separated by an interval of gorge cutting several times as long as the postglacial interval (page 16).

The statement is warranted, therefore, that

“Characteristics of Existing Glaciers,” 1911.

these valleys have been profoundly modified by glacial erosion, both by deepening and broadening (page 30).

But here, as in the process of glacial stream erosion, the bulk of the work was done by an earlier ice advance (page 31).

It is admitted that ice sheets may have some individuality and that successive sheets on the same territory may have somewhat different behavior and produce different effects, due to differences in the climatic, topographic and drift factors. But it does not seem reasonable that one ice sheet could deepen Seneca Valley 1,500 feet, while its successor did practically no eroding at all. If the Prewisconsin ice sheet had such remarkable excavating power it should have produced conspicuous erosional effects elsewhere than in the valleys, and specially in the southern part of the state, and should have piled heavy “old drift” deposits beyond the reach of the Wisconsin ice.

The drift burden of the Laurentian ice sheet is represented not merely by the mass of the moraines and the volume of detritus carried away by the glacial drainage, but also by the enormous bulk of drift built into the drumlins. Even if the drumlins were partly constructed by the earlier ice sheet they can not, because of their location, represent any product of deep erosion of the sections of Seneca and Cayuga valleys in question. There are no heavy moraine deposits south of the Valley-Heads moraine, for the terminal moraine is not massive, and the ancient drift in Pennsylvania and New Jersey is not excessive in volume. The only other disposal of the great volume of *débris* that should have been produced by deepening of the valleys 1,500 feet must have been by outwash of the glacial drainage. But when the valley-train and outwash deposits attributed to the latest ice are considered there is no

very large volume left to represent any earlier drainage.

The entire argument for deep ice erosion in the Finger Lake region is based on physiographic features, hanging valleys and "oversteepened" valley walls. The writer believes that sufficient attention has not been given to the effects of Prepleistocene drainage in connection with the climatic, topographic and diastrophic factors. The high elevation of the northern part of the continent in Tertiary time seems to be a fact, and accompanied by warm climate. If necessary to explain phenomena we may assume effective vertical movements in our region. The Tertiary was certainly a time of vigorous drainage and remarkable valley-cutting in northern lands. When the fiord valleys were making in other lands what was doing here? Undoubtedly our rivers were also active, and the deep valleys of central New York are one result.

At the last Baltimore meeting of the society the writer exhibited a series of maps suggesting the drainage evolution in New York.<sup>7</sup> The high "Hung-up" valleys with northeast by southwest direction, and mostly without present streams, seem to be an inheritance from the primitive drainage on the new land surface. The drainage lines of the upper tributaries to the Delaware and Susquehanna rivers preserve their original direction. During some Prepleistocene time the development of subsequent valleys along the strike of the thick and weak Ontario strata resulted in a great east and west valley, carrying a great trunk stream, the hypothetical Ontarian River. Into this valley was drawn from the south, as obsequent streams, all the drainage of western and central New York and the adjacent territory of northern Pennsylvania. The Susquehanna River turned northward

at Elmira and occupied the Seneca Valley, which probably accounts for the excessive depth of the valley, a drilling at Watkins of 1,200 feet failing to reach rock. The Genesee River is the one stream which fully represents the Preglacial northward flow, having held to its northward direction clear across the state in spite of the tendency of glaciation to force it into southward flow. All the other drainage of south-central New York was forced to southward escape, mostly in tribute to the Susquehanna and through the new rock gorge at Towanda, Pa. A late and probably rapid land uplift, rejuvenating the obsequent drainage, will probably be found to satisfactorily account for the great depth and other anomalous features that have been used as arguments for deep glacial erosion in New York. Interglacial drainage may also be important in this work.

It will now be understood that when the earliest ice sheet invaded New York it found a topography unlike the present, a remarkable series of parallel, deep, open, north-sloping valleys that headed southward, the larger ones in Pennsylvania. The present divides in the valleys are due to the moraine fillings left by the ice. The deep canyon-like valleys were occupied by the glacier and some abrasion and smoothing of the walls was inevitable. But it should not be forgotten that the ice tongues in these valleys were not mountain glaciers, but merely lobations of a drift-burdened margin of an ice sheet moving on an upslope. Conceding some erosive power to the ice tongues in the valley, then instead of deepening the valleys and oversteepening the walls and so producing the present convex cross-profiles they should have cut the walls and widened the valleys and produced concave profiles. In the work of stream glaciers convexity of valley slope is succeeded by concavity. In final word, to

<sup>7</sup> *Geol. Soc. Am., Bull.*, Vol. 20, pp. 668-670, 1910.

a discussion already too long, in the opinion of the writer all the facts and philosophy of ice erosion argue against deep glacial erosion in the Finger Lake valleys.

One interesting product of glacial erosion is to be noted. These are some hills which have the form and attitude of true drumlins, but which are composed of soft shale, shaped into drumlin form. These rocdrumlins will be described later.

#### CONSTRUCTIONAL WORK.

*Subglacial: Rocrumlins.*—The general drift sheet presents no special features meriting description at this time. The important subglacial deposits are the rocdrumlins. New York state probably has the best display of these interesting hills of any district in the world; in number, variety of form, variety in orientation, difference in composition and in the clear relationship to the correlating moraines.

Much space might be given to description of these singular and most beautiful hills, but they have already been quite fully described in a Bulletin of the State Museum.<sup>8</sup>

Possibly in other regions there may be drumlins produced by the ice overriding and reshaping moraines, but all the true drumlins observed in New York are certainly constructional in their origin. The New York moraines are mostly water-laid drift, especially north of the divide, the débris in the ice being largely grasped by the glacial drainage. If the drumlins were moraine accumulations they would have morainal composition and structure. On the contrary, they are very compact till, distinctly bedded with concentric structure. The best exhibition of the bedding is shown along the shore of Lake Ontario, between Sodus and Oswego, where the undercutting by the waves has dissected numerous drum-

lins from top to bottom and in different directions. Sand or gravel within the mass of the drumlin is of infrequent occurrence, though some of the drumlins between Clyde and Savannah hold considerable sand in their superficial layers. Many drumlins exhibit decided difference between the deeper and the superficial till, sometimes so pronounced as to suggest two epochs of construction.

Along the belt of outcrop of the soft Salina shales there are drumlins which have a shale base, and perhaps some with a shale core. Fifteen miles northwest of Syracuse and west of Baldwinsville the drumlin forms are entirely shale. The deeply weathered clay rock supplied to the ice sheet a plastic material similar in its behavior to the ground moraine. These hills are not true drumlins. They are wholly erosional in origin, as indeed are the true drumlins in their shaping. We have called them rocdrumlins, using the Celtic prefix. It is possible that similar forms will be found in the Champlain-Hudson Valley, shaped out of the softer Ordovician shales. The ice sheet does not appear to have had scraping force sufficient to shape into the drumlin curve any rock hills of harder materials than soft shale, though bosses of crystalline rocks in the St. Lawrence Valley and other districts of long-continued abrasion are rounded and smoothed on the struck sides.

The mechanics of drumlin construction is a complex problem. The required cooperation and balancing of several dynamic factors make the drumlins exceptional features even in the glaciated territory. The more important constructional factors appear to be: (1) An excessive amount of drift; (2) the drift of clayey or adhesive and plastic material; (3) such thickness of marginal ice and with such relation to the rearward ice body that the whole depth of

<sup>8</sup>N. Y. State Museum Bull. 111, 1907.

ice accepts a thrustal movement, producing a sliding motion of the ice in ground-contact; (4) such temperature or physical condition as to allow plasticity and some differential motion within the ice, essential for the overriding of the growing obstruction instead of its removal. Here is found a singular balancing of two opposing factors, rigidity and plasticity; rigidity holding the ice mass, as a whole, to its thrustal motion, while at the same time bands or currents within the ice sheet have unequal motion, permitting the curving or arching flow over the growing hill of drift. The drumlin-making process appears to be a plastering-on and a rubbing-down, depending on the condition of more friction between clay and clay than between clay and ice. The resulting form of the growing obstruction is that which offers the greatest resistance to removal, or the least resistance to the passage of the ice over it. The molding action of the ice sheet is well shown by the minor ridges in some districts, the secondary and tertiary inferior ridges lying on the flanks of or between the primary ridges suggest the wood-molding struck in the planing mill.

The complex of forces and conditions necessary for drumlin construction explains their peculiar distribution, orientation and form. In the western half of New York the rich display of drumlins (nearly a thousand ridges being shown by the contours on the Palmyra sheet alone) is practically limited to the territory north of the divide, where the drift was profuse and the thinning ice was pushing on an upslope. In the Ontario basin their attitude or direction of the major axis is radial to the middle of the basin, varying from due east to southwest. In the Erie basin a group about Chautauqua Lake points southeast, while in the Mohawk valley north of Richfield Springs a group has westward point-

ing. In the Champlain and Hudson valleys the drumlins point southward. In the St. Lawrence Valley they show the latest and spreading flow. Everywhere they show the later ice-flow direction.

The most typical drumlin form, that which seems to express the most vigorous action and effective balancing of the several factors, is an elongated oval with steep convex side slopes, and these are found in the middle of the drumlin belt. New York exhibits all possible variations from this form. The shorter ridges, sometimes approaching dome-shape, but usually with some irregularity or lack of symmetry, are found at the north or proximate side of the drumlin belt, which suggests that the broad form is the product of less perfect work. The much elongated and attenuated ridges lie at the south or ultimate side of the belt and indicate the more uniform or rigid flow of the ice sheet with deficiency of drift.

In the western end of the state the till sheet over large areas has been rubbed into a fluted or washboard form on a large scale, but with low relief. It is inferred that this drumlinized surface with ribs one fourth to one half mile wide represents the work of thick ice, having great weight and vertical pressure, with diminished plasticity and carrying only a moderate load of drift. The direction of the flutings, southwestward, is the direction of flow of the maximum ice body.

In central New York we have been able to definitely correlate the drumlin belt with its synchronous moraine; to determine the position of the ice front during the drumlin-making episode. On the meridian of Seneca and Cayuga lakes the drumlins of the north side of the belt are more scattering and irregular in form. In the middle of the belt they are close-set, typical, elongated ovals. Southward they become close-set ridges with secondary flutings; while at

the south edge of the belt they are slender ridges and flutings, too attenuated to be represented by the twenty-foot contours of the topographic sheets. It would require at least five-foot contours to show the frontal drumlinized surface. Two miles in front of the most southerly ridges indicated on the Geneva sheet lies a weak but definite moraine. It is weak because the ice had plastered its load of drift into the drumlins.

From the relation of the ice front to the glacial waters and other data it has been roughly estimated that the thickness of the ice over the middle of the drumlin belt was about 900 feet, or more than 700 feet over the tops of the highest drumlins.

*Marginal: Moraines.*—The only map published to the present time that shows moraines in detail is that by Tarr in the Watkins Glen-Catatonk folio (No. 169), which is accompanied by good description. This map, *Surficial Geology*, covers eight quadrangles of the south-central portion of the state and includes the upper (southern) ends of the Seneca and Cayuga valleys. Except a few fragmentary moraines in the east and west stretch of the Susquehanna and Chemung valleys there are almost no moraines south of the divide, as already noted in this writing. The lines of drift massing show decided lobation of the ice in the valleys north of the divide and conformity to the land surface. The plastic ice was here flowing on its own deposits and had no erosive power. Probably the only moraines in the state that can properly be called "lateral" lie in these valleys.

In the west half of the state the heavier or more conspicuous morainic belts have been approximately located though little precise mapping has been attempted. The most recent and definite is by Leverett,<sup>9</sup> and a sketch map, Fig. 11, page 15, in the

Folio 169. These morainic belts clearly show the larger lobation of the waning ice sheet in the Ontario and Erie basins.

In the east half of the state the moraines have been located in only few places, excepting the terminal moraine. In the Hudson and Champlain valleys Woodworth has recognized some fragments and ice-contacts. This difference in moraine development between the two parts of the state is due to the difference in the gross topography. A glance at the map shows that on the Hudson-Champlain meridian the distance covered by the receding ice front is greater than in the Ontario basin, so spreading the drift over more area. The rocks in the east part of the state are more resistant to erosion, due to kind and structure. The Hudson ice lobe and its successor in the Champlain Valley were always faced by ocean waters and the terminal drift in the bottom section of the great valley was mostly scattered and buried under the water deposits. On the high grounds east and west of the marine inlet the surfaces are so rough, or even mountainous, that the moraine deposits lack continuity and volume. It will be very difficult to trace morainic belts across the Hudson-Champlain Valley with certainty, though it is important to know the lines of the receding ice front.

#### WORK OF GLACIAL WATERS

*Erosional Work of Streams. Normal Drainage.*—It is apparent that the flow of glacial waters freely away from the ice could occur only south of the divide, and as the present divide was established by morainal filling and lies north of the preglacial divide much of the southward flow was drainage of ice-dammed waters, and that some of the present south-leading channels were cut by the glacial waters. The preglacial flow of the main streams

<sup>9</sup> U. S. Geol. Surv., Monograph XLI., 1902.

was northward, but the tributaries had various directions. The glacial drainage took advantage of the favoring valleys and connected them into sequence of southward flow. Tarr thought that the work of stream diversion and of channel erosion was mainly Prewisconsin, for the district described in the Folio 169 (page 30). He specially cites the outlet of Cayuga Lake, the gorge of Tioughnioga creek and the gorge of Chemung River behind Hawes hill, west of Elmira. The copious waters from the waning Laurentian ice sheet were supplied with such volume of detritus that they were largely aggrading agents. It is possible that the south-leading valleys were mostly established by Prewisconsin glacial drainage and that the work of the latest glacial floods was chiefly transportative. In the eastern half of the state the glacial outflow was freely into the Susquehanna and Delaware escape or into the Hudson-Champlain marine inlet, so there was no necessity for cutting new channels.

The heaviest normal drainage was that in south-central New York, concentrated in the Susquehanna, which cut the gorge south of Sayre, Pa., and the river which drained Lake Iroquois through the Mohawk Valley, the Iromohawk. This great river was the predecessor of the St. Lawrence, which it probably exceeded in volume, as it carried not only the outflow of the glacial Great Lakes, but the copious waters from the glacial melting.

*Subglacial Drainage.*—This class of glacial streams has been noted chiefly in relation to eskers, which fall under another head in this writing. It is not likely that all eskers were laid down in the beds of streams actually beneath, or in tunnels under, the ice sheet, though some probably were. Probably most subglacial or englacial streams were full loaded with detritus, and it is not likely that many streams be-

neath the ice margin were so free of drift or under such hydraulic pressure as to seriously erode their beds. However, a few peculiar channels, or "dead" creeks, have been noted which have such form and relations as to suggest erosional flow beneath the stagnant margin of the ice. One of these bayou-like channels is that of Dead creek, a tributary of Seneca River, lying southwest of Baldwinsville, and mapped on the Baldwinsville sheet.

*Marginal Drainage.*—This class of drainage phenomena included many of the most conspicuous and interesting features connected with the disappearance of the ice sheet, and they have been the subject of much work by the writer. The ice-border drainage channels are important as they locate ice-front positions and determine the altitude of the glacial lakes which they drained. They are humanly, or economically, important since they have graded the ways for many lines of communication or transportation. And they are specially valuable for geologic instruction since they are widely distributed and easily recognized products of long extinct agencies.

It is evident that stream flow along the ice margin could occur only where the land surface sloped toward the ice, and consequently only north of the divide. The remarkable physiography of the western half of the state favored the production of glacial lakes, which required outlet channels for the imprisoned waters.

The most notable series of ice-border drainage channels occur in five districts. (1) On the south slope of the Erie basin, where the ice-impounded waters in the north-sloping valleys escaped westward into the Erian glacial lakes. (2) Along the south slope of the Ontario basin the glacial waters found eastward escape toward the Mohawk-Hudson depression. (3) On the

Helderberg scarp, west of Albany, the waters of the Ontario and Mohawk basins escaped southward into the Hudson marine inlet. (4) In the district about Rome, at the east end of the Ontario basin, the waters from both the north and the west flowed along the sides of the ice lobe to reach the Mohawk Valley. (5) On the north and west sides of the Lowville highland the waters of the southwestern Adirondacks and the Black Valley forced their passage into Lake Iroquois.

The channels leading east through central New York, more conspicuously developed in the Syracuse district, were the predecessors of Niagara River in their function, the equal of Niagara in volume, and the rival of Niagara in cataract phenomena.

The successor of the Iromohawk and the immediate predecessor of the St. Lawrence was the outlet river of the second Lake Iroquois. This flowed across the north point of the Adirondack highland, at Covey Gulf, on the international boundary, with further flow in ice border channels along the slopes northwest of Plattsburg, on the Dannemora and Moors quadrangles.

#### CONSTRUCTIONAL WORK OF STREAMS.

*Subglacial: Eskers.*—The singular ridges of gravel, the laggard material in the beds of glacial streams, are well represented in the western part of the state and occur in the eastern part. Those lying in the northwestern section of the state have been studied, but the results are not published. Tarr describes in Folio 169 (pp. 22-23) several which lie in the Susquehanna drainage territory, and of large dimensions, and Carney recognizes nine on the Moravia quadrangle. Eskers may not occur on southward slopes where the glacial streams had steeper gradient and free flow, but in localities where the ice margin was com-

paratively stagnant and the drainage was sluggish.

The argument for subglacial origin of eskers finds some support in the New York examples. Tarr regards some of those in the Susquehanna district as certainly made by subglacial streams. An esker four miles east of Clayton was deposited about 350 feet beneath the level of Lake Iroquois, which was laving the ice front, and it is difficult to explain how it could have been constructed and its definite ridge-form preserved unless it was built directly on the ground. The same argument applies to the Ingoraham esker, north of Plattsburg.

*Extraglacial: Kames.*—Isolated mounds of sand or gravel are usually embryo deltas of glacial streams, and are commonly associated with eskers. By linear multiplication they not infrequently grade into esker ridges.

As kames are built at the debouchure of glacial streams, they indicate positions of the ice edge. Areas of kames lie in belts of recessional moraines, and indeed constitute a large part of the New York moraines. The glacial debris which was not spread as the till sheet or rubbed into drumlins was largely gathered up by the drainage and dropped as some form of water-laid drift.

In western New York a few large kame areas are not closely connected or clearly associated with any conspicuous moraine belt, but nevertheless must represent recessional moraine. It is possible that some smaller kames might have been built by land drainage into lateral glacial lakelets, but detritus from land erosion must commonly have produced deltas or sandplains and be easily recognized by form and association. The great development of kames, at least in western New York, is north of the divide, and they were built in the waters of glacial lakes. This association with standing waters is so pronounced

that it gives force to the idea that all typical kames are formed by streams debouching into water bodies, and sometimes by subglacial streams under hydraulic pressure. Streams debouching on the land would naturally produce either outwash plains or valley trains. The fact that basins or kettles, believed to be due to melting out of buried ice blocks, are usually abundant in areas of kames, seems to prove that the materials were laid down in standing water in close association with the stagnant ice margin, either on the ice or in hollows and valleys and reentrants in the ice.

*Extraglacial: Outwash Plains.*—These are the gravel and sand deposits spread out in front of the glacier by the outflow of the glacial streams and which can not be classed on the one hand as deltas or on the other as valley trains. Water-laid drift in facial contact or close association with the moraines and which can not be distinguished either as delta, kame or valley train, may safely be put in the indefinite class of outwash gravel plains. North of the divide where built in lakes they grade into deltas and kames. South of the divide they constitute most of the valley fillings, especially of the broader valleys which lay athwart the direction of ice flow.

A not uncommon feature of the gravel plains and one which shows the close relation to the glacier front, is the existence of ice-block kettles. The term "pitted plain" has been applied to the sand plains with numerous kettles. Another feature indicating their genesis is the preservation in some cases of the ice-contact slope. The outwash sand and gravel plains are more common in the southwest part of the state and in the Mohawk Valley. In the highlands the drainage was too free and vigorous. In the Champlain-Hudson Valley, lower levels, the sea-level waters distributed the glacial stream detritus, or it was

buried under the deluge of sand contributed by the rivers since the ice disappeared. The very extensive sandplains on both sides of the Hudson River and Lake Champlain, for example, the Saratoga district, must be classed as marine deltas. But on the walls of the great valley above the marine plain Woodworth has noted ice-contact slopes of glacial outwash deposits. In the Susquehanna district Tarr found numerous plains of this class.

*Extraglacial: Valley-Trains.*—South of the divide, where the drainage had free escape, some detrital filling of the valleys is common and occasionally abundant. The high-level flood plains along the valley sides and the elevated deltas of lateral tributaries testify to the glacial floods and their burden of detritus. The deposit by glacial flow is of course intermingled with and in places buried under land stream detritus. The valley trains may be regarded as heading in outwash plains, and one might regard the glacial gravel deposits in the entire length of the valleys north of the terminal moraine as outwash. This view would restrict the true valley-trains to the fillings of valleys beyond the terminal moraine or reach of the ice sheet. In this latter view the valley-train drift would occur in New York only along the south side of Long Island, and in the small area south of the Alleghany River.

HERMAN L. FAIRCHILD

UNIVERSITY OF ROCHESTER

(To be concluded)

#### SCIENTIFIC NOTES AND NEWS

PROFESSOR WILLY WIEN, of Würzburg, will deliver at Columbia University, during the month of April, a series of lectures on recent developments in theoretical physics. Professor Wien received the Nobel prize in physics in 1911 and is well known for his researches in radiation and the electrical constitution of matter.

On the occasion of the dedication of the new building of the Medical Department of the University of Georgia, on January 29, the LL.D. degree was conferred on Dr. William M. Polk, dean of Cornell University Medical College, and Dr. J. A. Witherspoon, president-elect of the American Medical Association.

DR. F. KÖRTE, who has been an important figure in the development of medicine in Germany, celebrated, on January 16, his ninety-fifth birthday.

KING CHRISTIAN has decorated Dr. V. Poulsen and Professor P. O. Pedersen with the medal of merit in gold on account of the honor they have brought to Denmark by their work in connection with wireless telegraphy and telegraphones.

M. B. BAILLAUD, director of the Paris Observatory, has been elected president, and M. H. Deslandres, director of the Meudon Observatory, vice-president, of the Paris Bureau des Longitudes for 1913.

DR. EBERHARD RIMANN, of the Technical Institute at Dresden, has been appointed director of the Geological Survey at Brazil in succession to Professor E. Hussac.

DR. E. M. KINDLE, since 1901 paleontologist in the U. S. Geological Survey, has accepted a similar position on the Geological Survey of Canada.

PROFESSOR H. E. CLIFFORD, who holds the McKay professorship of electrical engineering at Harvard University, will go in the second half-year to Annapolis, to organize graduate study in electrical engineering at the Naval Academy.

RICHARD M. HOLMAN, B.A. (Stanford, '07), senior instructor in botany, University of the Philippines, stationed from June, 1910, to June, 1912, at the College of Agriculture, Los Banos, Philippine Islands, is on leave of absence which extends to September, 1913. He is at present engaged in graduate study at Leipzig University.

PROFESSOR JAMES F. KEMP, of Columbia University, delivered a short course of lectures during the month of January, in the Faculty of Applied Science at McGill University, on

"The Services of Geology to the Mining Industry."

DR. MARTIN FISCHER, of the University of Cincinnati, delivered the address at the third winter commencement of St. Louis University School of Medicine, January 30, on the subject, "Principles of Treatment of Edema and Nephritis."

DURING the week of January 13 to 18, Mr. Vilhjalmer Stefansson visited the University of North Dakota, at which he was a former student, and delivered a series of three lectures, as follows: January 13, "Five Years of Arctic Exploration"; January 14, "The Discovery of the Blond Eskimo"; January 15, "The Mind of Primitive Man." Later in the week he was a guest of the Icelandic Society, of which he is a member.

ON January 29, Dr. Joseph Barrell, professor of structural geology in Yale University, gave an illustrated lecture on "A Reconstruction of Connecticut's Geologic Past," under the auspices of the Yale chapter of Sigma Xi.

THE seventh of the present course of Harvey Society lectures will be given at the New York Academy of Medicine on February 15, by Dr. Theodore C. Janeway, of Columbia University, on "Nephritic Hypertension: Clinical and Experimental Studies."

THE Mutual Life Insurance Company is providing a series of lectures in New York City. The lecture of January 29 was delivered by Surgeon-General Rupert Blue, United States Public Health Service, who spoke on the bubonic plague and other contagious diseases.

PROFESSOR ISAIAH BOWMAN, of Yale University, delivered a lecture on "The Physiography of the Central Andes" before the Geological Department of Columbia University on January 28.

DR. ORVILLE HORWITZ, until his illness head of the department of Genito-Urinal Surgery in Jefferson Medical College, Philadelphia, died on January 28, aged fifty-five years.

DR. JAMES P. TUTTLE, fifty-six years of age, a practising surgeon and professor emeritus

of surgery in the Polyclinic Hospital, New York, died on January 30.

DR. O. T. WILLIAMS, lecturer on pharmacology and demonstrator of biochemistry in the University of Liverpool, has died at the age of thirty-five years.

PROFESSOR BINZ, who held the chair of pharmacology at Bonn, has died at the age of eighty years.

DR. F. TELLER, chief geologist at the "Geologische Reichsanstalt," Vienna, and member of the Vienna Academy of Sciences, died on January 10, in his sixty-first year.

DR. R. COLLETT, professor of zoology in the University of Christiania, has died at the age of seventy years.

DR. AUGUSTUS WITKOWSKI, professor of experimental physics in the University of Cracow, died on January 21, at fifty-eight years of age.

THE Archduke Rainer, the oldest member of the Imperial Austro-Hungarian family, who died on January 27, at eighty-five years of age, was actively interested in scientific and artistic activity. Foreign journals state that at the Vienna Academy of Sciences, of which he was curator, he never missed an important sitting, while the Austrian museums owed their development largely to his support.

IN the Senate of the United States on January 24 Mr. Cummins submitted the following resolution, which was considered and agreed to:

*Resolved*, That the Committee on Naval Affairs is hereby authorized and directed to investigate the affairs of the Naval Observatory and its relation to the American Ephemeris and Nautical Almanac; and, further, to inquire into the wisdom and propriety of placing the management of the Naval Observatory in the hands of scientists, without regard to their connection with the Navy of the United States.

*Resolved further*, That the said committee be directed to make report of the matters herein referred to it as soon as practicable.

THE Harriman Research Laboratory, which was established in New York City in 1910 and is maintained by Mrs. E. H. Harriman

for the study of chemical problems connected with disease and owns and operates a building on the grounds of Roosevelt Hospital, has been incorporated.

A GOLD medal is offered by the American Laryngological Association for the best essay pertaining to laryngology or rhinology, preference being given to essays offering new suggestions of practical value arising from original work.

THE heirs of Herr Adolf Schwabacher, the Berlin banker, have established a foundation with 100,000 Marks, the income of which will be used to confer a prize in medicine every five years.

THE Astronomical Society of Mexico has decided, beginning from 1913, to offer a medal and diploma to any astronomer who discovers a comet. The medal will bear the name of "Carolina Herschel Medal."

THE ninth International Physiological Congress will be held at Groningen September 2-6 under the presidency of Professor H. J. Hamburger.

AT a special general meeting of the Royal Geographical Society, on January 15, the president, Lord Curzon, of Kedleston, moved the resolution: "That the society approve of the election of women as fellows," and it was carried by 130 votes to 51.

THE Jesup lectures on Heredity and Sex, by Dr. Thomas H. Morgan, professor of experimental zoology in Columbia University, are now being given in the lecture hall of the Museum of Natural History on Wednesday evenings at 8:15. The subjects are as follows:

February 5—"The Evolution of Sex."

February 12—"The Mechanism of Sex Determination."

February 19—"The Mendelian Principles of Heredity and their Bearing on Sex."

February 26—"Secondary Sexual Characters and their Relation to Darwin's Theory of Sexual Selection."

March 5—"The Effects of Castration and of Grafting on the Secondary Sexual Characters."

March 12—"Parthenogenesis and Sex."

March 19—"Inbreeding and Fertility."

March 26—"Special Cases of Sex Inheritance."

THE Norman W. Harris lectures of Northwestern University will this year be given by Dr. J. S. Ames, professor of physics in Johns Hopkins University. The series, comprising six lectures on the subject "The Constitution of Matter," is as follows:

February 24—"General Properties of Matter; Mass."

February 25—"Corpuscles and Atoms; Electrical Mass."

February 26—"Radioactivity; Gravitation."

February 27—"Radiation; Formation of Molecules; Elasticity."

February 28—"Properties of Metals; Thermionics."

March 1—"Models of Atoms; Conclusion."

WE learn from the *Journal* of the American Medical Association that on January 25 the American Society for Physicians' Study Travels, with national headquarters in Philadelphia and proposed branches throughout the United States, was formally organized at a meeting of prominent medical men at Philadelphia. Dr. James M. Anders was elected president and Dr. Albert Bernheim was chosen as secretary. The society proposes to send travel parties to foreign countries to report on the methods of leading medical men and scientists in Europe and South America. All physicians and scientific men qualified to become affiliated with the American Medical Association will be eligible for membership, and also associate and honorary members will be elected among the prominent medical and non-medical men of this and foreign countries.

ON February 3 the city of Providence passed a resolution accepting as a gift from the Audubon Society of Rhode Island the Manly-Hardy collection of North American birds and also as a gift from Mr. Horace F. Carpenter his collection of shells and minerals with a library descriptive of the same. The conditions of the gifts are that they shall be properly cared for and exhibited at the Park Museum within three years from date of acceptance. This means that the city will erect an addition to the museum almost as large as the present structure, equipped to exhibit the

collections. The Manly-Hardy collection of North American birds, which has just been purchased by the Audubon Society of Rhode Island through subscriptions of its members and friends, is one of the most valuable private collections in existence and represents thirty-three consecutive years of work on the part of Mr. Hardy and his daughter, Mrs. Fannie Hardy Eckstorm. The collection is remarkable for its many specimens in breeding plumage, for some extinct and for numerous rare species. The Carpenter collection of shells and minerals represents about fifty years' work by Mr. Horace F. Carpenter, of Providence, and contains over three thousand species of shells, about five hundred different kinds of minerals and a library valued at over \$2,000.

#### UNIVERSITY AND EDUCATIONAL NEWS

OHIO-MIAMI MEDICAL COLLEGE of the University of Cincinnati, has received \$125,000 from a donor whose name is being withheld. An effort is being made to raise an endowment fund of \$1,000,000.

DURING the past year three wills, involving property valued at \$125,000, have been probated in favor of Knox College. About half of this amount becomes available immediately for the endowment of a professorship in one of the departments of science, while the remainder is held in trust during the lifetime of the widow of one of the testators.

MR. EUGENE MEYER and his wife, of New York, have given Cornell University \$10,000 to endow a fellowship in memory of their son, Edgar J. Meyer, who graduated from Sibley College in the class of 1905 and whose life was lost by the sinking of the *Titanic*. The purpose of the fellowship is to encourage research in mechanical and electrical engineering.

THE *Journal* of the American Medical Association states that the College of Physicians and Surgeons of Chicago again passes under the control of the University of Illinois. This time it is a gift to the state institution partly

by the stockholders and partly by the alumni who purchased the stock not donated. The medical school has for several years held a contractual relationship with the University of Illinois, but that relationship was cancelled last spring. By the present transfer of all the stock, however, the medical school becomes an organic department of the university.

An administrative committee of the faculty of the Johns Hopkins University has been appointed by the trustees to conduct the affairs of the university until a president is appointed. The chairman is Dr. William H. Welch, and the other members are Professors B. L. Gildersleeve, W. W. Willoughby, W. B. Clark, J. S. Ames, W. H. Howell and E. H. Griffin.

Dr. J. W. W. STEPHENS has been appointed to the Sir Alfred Jones Chair of Tropical Medicine at Liverpool University, vacant through the resignation of Sir Ronald Ross, who has gone to live in London.

#### DISCUSSION AND CORRESPONDENCE

##### UNIVERSITY REGISTRATION STATISTICS

TO THE EDITOR OF SCIENCE: Unfortunately I was unable to see the proof of my contribution on "University Registration Statistics" to your issue of December 27, 1912, and, as a result, several errors have crept into the compilation which I desire to correct herewith.

Since the detailed figures for the *University of Nebraska* were not available at the time the article went to press, this institution was omitted from the table, consequently the references in the body of the article should be to twenty-eight instead of to twenty-nine institutions. The missing *Nebraska* figures are as follows: college, men, 464; college, women, 617; agriculture, 328; art, 19; forestry, 64; graduate school (non professional), 164; law, 222; medicine, 159; pedagogy, 148; pharmacy, 32; scientific schools, 376. After deducting the double registration of 110, it leaves a total fall registration on November 1, 1912, of 2,483. Of the 486 summer session students, 158 returned in the fall, giving a grand total of 2,811 students for the year.

The fall total at the *University of California* is 4,585, and not 4,741; and that of *Columbia* is 6,148 and not 6,153. The dagger after "extension and similar courses" under the *University of California* should be a plus sign. The grand totals at *Columbia* should read as follows: 1912: 9,002, 1911: 7,938, 1910: 7,411, 1909: 6,132, 1908: 5,677, 1903: 4,557.

The *Indiana* figures should read as follows: College, men, 709; college, women, 438; art, 45; graduate school, 70; journalism, 67; law, 108; medicine, 140; music, 58; pedagogy, 144; deduct double registration, 354; total, 1,423; summer session, 1,197; deduct 280 students who returned for work in fall; grand total, 2,340. Both *Indiana* and *Nebraska* should be omitted on page 889 among those institutions which have more than 1,400 students registered in the college.

The *Johns Hopkins* grand total for November 1, 1912, should read 944, and that for 1911, 1,120.

At the *University of Minnesota* the item of double registration should read 175, instead of 319, thus making the grand total 3,737. This grand total is exclusive of 1,326 students registered in "extension and similar courses," but this latter category of students was included in the figures for 1903 and for 1908-1911.

The grand total enrollment at the *University of Texas* for November 1, 1909, was 2,512, 1908: 2,410, 1903: 1,309.

	1912	1911	1904
Amherst.....	429	464	412
Brown (incl. graduate school).....	934	933	988
Bryn Mawr (incl. graduate school).....	444	440	441
College of the City of New York.....	1,109		
Dartmouth (incl. eng., med., grad. stud., and commerce).....	1,294	1,385	926
Haverford.....	167	164	146
Lehigh.....	617	599	609
Massachusetts Institute of Technology.....	1,611	1,610	1,561
Mount Holyoke.....	748	771	674
Purdue.....	1,749	1,762	1,359
Smith.....	1,528	1,508	1,067

Wellesley.....	1,424	1,433	1,050
Wesleyan.....	410	395	305
Williams.....	521	533	443

These changes in the table naturally necessitate certain changes in the body of the article on pages 887 and 889.

The enrollment as of November 1, 1912, of a number of colleges for men and women, and schools of technology is given in the preceding table.

RUDOLF TOMBO, JR.

COLUMBIA UNIVERSITY

lications at hand. Dr. Ries has apparently made good use of the available literature both American and foreign and has condensed it into a volume whose usefulness, for the class of readers for which it is intended, is, I believe, enhanced by such condensation.

HENRY LEIGHTON

UNIVERSITY OF PITTSBURGH

#### BUILDING STONES AND CLAY PRODUCTS

In the issue of *SCIENCE* for December 27, 1912, there appeared a review by George P. Merrill of "Building Stones and Clay Products" by Heinrich Ries. It seems to me that the criticisms thus set forth in the review are a trifle harsh and I would like to call attention to a few statements which seem inaccurate. The reviewer says:

The portion devoted to stone contains nothing that is not to be found in other easily available works.

The fact that the work contains much information taken from American and foreign publications not even to be obtained in such a library as the Carnegie Library of Pittsburgh, would indicate that the information is not all *easily* available, while, in truth, a large part of it is practically *unavailable* to many of those who will make use of the book.

The second portion of the book, that devoted to clay products, he states "is little more than an abbreviation of what the author has already included in his well-known work, 'Clays, their Origin, Properties and Uses.'" In his work on clays, Dr. Ries devotes 42 pages to structural clay products, while in the book under criticism, 130 pages are given over to the subject. The new work contains 34 illustrations concerning clay products, only 6 of which were given in the book on clays. The section on clay products, if compared at all with the similar portion of the earlier book, is a decided *amplification* instead of an *abbreviation*.

All works of this character must be largely compilations and their value depends largely on the arrangement and the care in selecting the proper material from the wealth of pub-

#### QUOTATIONS

CORRESPONDENCE BETWEEN THE PRESIDENT OF WESLEYAN UNIVERSITY AND THE PROFESSOR OF ECONOMICS AND SOCIAL SCIENCE<sup>1</sup>

*My Dear Prof. Fisher:*—The press, far and wide, contain articles relative to remarks in reference to the churches of the country, reputed to have been uttered by you in a recent address in Hartford. I desire to know whether or not you have been correctly reported. If you have been incorrectly reported, will you please give me an exact statement of what you did say?

Sincerely yours,

WILLIAM ARNOLD SHANKLIN

*My Dear Dr. Shanklin:*—In reply to your letter just received I would say that the report of my remarks before The Get Together Club in Hartford, last Wednesday evening, was substantially misleading. Partly by the omission of qualifying statements which made the setting and shaped the interpretation, partly by ascribing to me words and utterances which were not mine at all, and perhaps partly by the striking headlines which raised brief incidental remarks into the prominence of a principal theme, the original report, upon which apparently many newspaper conclusions and comments have been based—as I should judge—decidedly unfair. This judgment of mine is confirmed in some degree at least, by the fact that the paper in which the report appeared was constrained by criticism in Hartford to offer me an opportunity to make corrections. There was, however, a large underlying element of truth in the report. I did not say that I would "throw Sunday wide open" or anything else of closely similar meaning. But I did say that I would allow very great freedom of Sunday observance, allowing a man pretty nearly anything that did not disturb the religious or other use of the day by others. I did say that I saw no religious inconsistency in

<sup>1</sup>The letters are all dated from Middletown on January 27.

a man's having an uproarious good time on Sunday; but I added that there should be no disturbance of the religious or other duties of the day by others. I did say that "I would," or that "I believe that I would" close up the churches temporarily, as an experiment. But I stated my reasons, with emphasis, because so many good, religious people have come to think of church going as a great part of the whole religious duty, and because, if there were no churches open for a time, these people would be constrained to turn to more important religious duties, of kindly service and the like. Just here I quoted the declaration of James as to the meaning of religion pure and undefiled.

The above will perhaps enable you to judge for yourself as to the degree of accuracy with which I was reported; but for a slight amplification of which I have just written, I am enclosing a copy of a letter which I sent in correction of the first report, and which was printed in the paper first reporting me, in its issue of last Saturday morning, January 25th.

Of course, not even all of what I am now placing at your disposal can make entirely clear my general attitude on Sunday observance; but it is probably quite enough to make you to see how and in what light I stood last Wednesday evening. And that, I am sure, is all of your present wants.

Very sincerely yours,

WILLARD C. FISHER

*My Dear Prof. Fisher:*—Your letter of this date is just received. Even after consideration of your explanation of your position, I find it difficult to believe that any one with a just appreciation of the work which the churches have done and are doing for the religious and moral life of the community, could seriously propose the closing of the churches, even as a temporary experiment. I am constrained to the conviction that your attitude in the matter is so far out of harmony with the spirit of the college, which, though in no wise sectarian, is and always has been profoundly in sympathy with Christian churches, that your continuance in your present official position is undesirable for the college or for yourself. I feel therefore compelled to request you to offer your resignation.

Most sincerely yours,

WILLIAM ARNOLD SHANKLIN

*My Dear Dr. Shanklin:*—Of course I shall respond at once to your request for my resignation.

Here it is. It is given cheerfully, I trust, and in full appreciation of the situation. I do not expect, I do not even undertake, to frame for myself a judgment as to what I might think the correct course for the college to take in such a case. But my judgment is not needed and it might be biased. I am, however, free enough from prejudice to see very clearly that a college with the history and the constituency and support of Wesleyan, is not exactly the place for a man who holds such views as mine, and who can not suppress them. I leave the college, therefore, without a trace of ill will toward anybody connected with it. Indeed I go with the warmest wishes for the institution to which I have given the twenty best years of my life.

Very cordially yours,

WILLARD C. FISHER

*My Dear Prof. Fisher:*—I have your favor, resigning from the faculty of Wesleyan University. I hereby release you from your duties, pending the presentation of your resignation to the board of trustees. I shall recommend that your salary be paid in full for the present academic year.

Appreciating your spirit of good will to the college, I am,

Most sincerely yours,

WILLIAM ARNOLD SHANKLIN

#### SCIENTIFIC BOOKS

*Manual of Conchology.* Vol. XXI. Achatinellidæ (Amastrinæ). By ALPHEUS HYATT and HENRY A. PILSBRY. Leptachatina by C. MONTAGUE COOKE. Philadelphia. 1911.

The "Manual of Conchology," founded many years ago by George W. Tryon, was designed to include descriptions of all the known living Mollusca. In Tryon's day it was essentially a compilation, but even so quite invaluable to conchologists. When Tryon died, and Dr. H. A. Pilsbry took his place, the character of the work changed, and the new volumes came more and more to represent exhaustive original research. The treatment of the Helicidæ, for example, put the whole subject on a new footing, and stands to-day as one of the great classics of malacology. Naturally the later parts have contained descriptions of fewer species than the early ones, the more elaborate treatment requiring more space;

hence the progress through families and genera has been much slower. On the other hand, considering the character of the work and the numerous illustrations, we may well marvel at the size of the yearly volumes, representing an amount of labor which few of us could undertake, even if possessing the necessary skill.

Professor Alpheus Hyatt died in 1902, leaving a quantity of unpublished manuscript on the Achatinellidæ, those remarkably varied and interesting snails of the Hawaiian Islands. Some years later these materials were turned over to Professor Pilsbry to be incorporated in the Achatinellidæ of the "Manual." The finished work is accordingly issued under the names of Hyatt and Pilsbry, although the greater part is by the junior author. The large genus *Leptachatina* (92 pp.) is by Mr. C. M. Cooke, of the Bishop Museum, Honolulu. The Achatinellidæ consist of two subfamilies, the arboreal Achatinellinæ, with usually light or brightly colored shells, and the mainly terrestrial Amastrinæ. The whole family is confined to the Hawaiian Islands, excepting the genus *Fernandezia* from the island of Juan Fernandez, which is located in the group provisionally, in the absence of any knowledge of the soft anatomy. The volume under review contains only the Amastrinæ; before the Achatinellinæ are described Dr. Pilsbry will himself visit the islands, and gain a first-hand knowledge of the subject.

The exhaustive and logical treatment, with the fine colored plates, enables us to gain a very good idea of the evolution and development of the Amastrinæ. The subfamily is to be divided into two very distinct tribes, which if given special names would be Leptachatinini and Amastrini. The first of these consists of oviparous forms, with shells closely resembling those of the circumpolar genus *Cochlicopa*. The second is to be divided into two series, both viviparous, but one elongate or Bulimoid, the other flattened or Helicoid. The flattened shells (three genera) were originally, when known, regarded as species of *Helix*, and the fact that they are indisputably Achatinellid shows how difficult it is to cor-

rectly place fossil land snails, known from the shells alone. One of the *Helix*-like genera was first (Ancey, 1889) named *Tropidoptera*, but was renamed *Pterodiscus* by Pilsbry on the ground that *Tropidoptera* was a homonym of the earlier Coleopterous *Tropidopterus*. In my opinion, *Tropidoptera* is a valid name,<sup>1</sup> the difference in the ending sufficing to prevent homonymy. I have long been familiar with the genera *Ancylus* (Mollusca) and *Ancyla* (Hymenoptera), and although using both names, have never found the slightest confusion to occur in my mind.

The number of new Amastrine species described is large, indicating that the previous work on the Hawaiian mollusca, although voluminous, did not nearly exhaust the subject. The parts of the work most interesting to the general zoologist are the introductory chapter by Dr. Pilsbry, and the appendix compiled from Hyatt's manuscripts. According to Professor Hyatt the animals migrated from island to island in ancient times, and in some cases he even indicates the probable landing places of the immigrants and their subsequent migrations. Dr. Pilsbry, while fully agreeing with many of Hyatt's views, especially those on taxonomy, holds that while the snails did indeed migrate in various ways, it was on dry land. That is to say, the Hawaiian Archipelago was once a single large island, which presently divided into two, later into four, and finally reached its present condition. Good arguments are given in support of this hypothesis, and one can not help feeling that they would have convinced Professor Hyatt, had he lived to consider them and to go over all the evidence available at the present time. It is impossible in a review to adequately discuss this matter, but it is very evident that the whole subject is of the greatest interest to students of evolution, and when worked out from every point of view, may give us a definite idea of the time required for the evolution of species of various groups in the Hawaiian Islands. It is supposed that the large island Hawaii had only its most north-

<sup>1</sup> It is well to note that it has been omitted from the "Index Zoologicus."

ern part above water until just before the present stage in the development of the archipelago. This idea seems to receive support from the fact that the Achatinellidae are almost confined to that part of the island, but it appears doubtful in view of the very large number of endemic Hymenoptera in Hawaii.

T. D. A. COCKERELL

*Géologie du Bassin de Paris.* Par M. PAUL LEMOINE. Paris. 1911. Pp. ii + 408; 137 figures; 9 maps.

Beginning with the classic "Description géologique des environs de Paris," by Cuvier and Brongniart, which reached a third edition as early as 1835, there have been a number of excellent general works on the geology of the Paris basin, that by Stanislas Meunier, first published in 1875, being perhaps the most used. Whatever the French do, they do well, and the Paris basin is such classic ground for the mesozoic and cenozoic geologist and paleontologist that the present work is of very great interest. That the book is well planned, well written and well illustrated is indeed but faint praise. M. Lemoine, who is vice-president of the Geological Society, has been working in the area for a number of years for the Geological Survey and is well equipped for the task of digesting the eight hundred odd memoirs treating of the area and combining their results with his own researches.

After three preliminary chapters devoted to an introduction for amateurs, and a historical, physiographic and tectonic discussion of the area, he plunges into the detailed geologic history of the basin, which commences with the Triassic. The Jurassic and Cretaceous of the Paris basin may be said to have furnished the standard for the world, as they have also so largely furnished the nomenclature, and these periods are treated at length. The very modern and altogether admirable work of the French paleontologists, particularly on the faunal facies and their correlation with particular sediments, is fully discussed and diagrammatically illustrated. Tertiary geology may be said to have been born in the Paris basin, even if Sir Charles Lyell was one of

the wise men present at the birth, and here again the treatment is full and accurate. The Eocene in particular, because of the alternation of marine faunas with littoral, lacustrine and continental deposits containing land plants and terrestrial mammals, deserves to be and is rapidly becoming the world standard. The time is not far distant when the French *étages* will be used in all countries where men interest themselves in Tertiary history. Osborn has applied them with considerable success in his discussion of American mammal horizons and they lend themselves with equal readiness to discussions of the paleobotanical history of North America.

The book contains nine double-page maps and 137 text figures, every one of which is excellent, and will prove a most useful traveling companion for visiting geologists. The author is to be warmly congratulated, and it is to be hoped that American students will not only read the book, but try to imitate its method in their own geological writing.

EDWARD W. BERRY

JOHNS HOPKINS UNIVERSITY

#### SCIENTIFIC JOURNALS AND ARTICLES

THE opening (January) number of Vol. 14 of the *Transactions of the American Mathematical Society* contains the following papers:

F. N. Cole: "The triad systems of thirteen letters."

H. S. White: "Triple systems as transformations, and their paths among triads."

G. D. Birkhoff: "Proof of Poincaré's geometric theorem."

S. Lefschetz: "On the existence of loci with given singularities."

B. H. Camp: "Singular multiple integrals, with applications to series."

Oswald Veblen: "Decomposition of an  $n$ -space by a polyhedron."

C. N. Moore: "On convergence factors in double series and the double Fourier series."

Virgil Snyder: "Algebraic surfaces invariant under an infinite discontinuous group of birational transformations. Second paper."

N. J. Lennes: "Note on Van Vleck's non-measurable sets."

T. H. Gronwall: "Some asymptotic expressions in the theory of numbers."

H. H. Mitchell: "Determination of the finite quaternary linear groups."

L. S. Dederick: "On the character of a transformation in the neighborhood of a point where its Jacobian vanishes."

THE January number (Vol. 19, No. 4) of the *Bulletin of the American Mathematical Society* contains: Report of the October meeting of the society, by F. N. Cole; Report of the October meeting of the San Francisco Section, by T. M. Putnam; Report of the Cambridge meeting of the International Congress of Mathematicians, Sections II.-IV., by Virgil Snyder; Report of the Münster meeting of the German Mathematical Society, by Virgil Snyder; "Shorter Notices": Hulburt's Differential and Integral Calculus, by D. D. Leib; Voigt's Theorie der Zahlreihen und der Reihengleichungen, by R. D. Carmichael; "Notes"; and "New Publications."

THE February number of the *Bulletin* contains: Report of the sixth regular meeting of the Southwestern Section, by J. N. Van der Vries; "Some special boundary problems in the theory of harmonic functions," by T. H. Gronwall; "Note on Fermat's last theorem," by R. D. Carmichael; "Integral equations": review of Lalesco's Introduction à la Théorie des Equations intégrales and Heywood and Frechet's L'Equation de Fredholm et ses Applications à la Physique mathématique, by W. R. Longley; "An advance in theoretical mechanics": review of E. and F. Cosserat's Théorie des Corps déformables, by E. B. Wilson; "Shorter Notices": Fagnano's Opere matematiche, Heath's Method of Archimedes recently discovered by Heiberg, and Höfler's Didaktik des mathematischen Unterrichts, by D. E. Smith; Poincaré's Wert der Wissenschaft, by J. B. Shaw; V. and K. Kommerell's Spezielle Flächen und Theorie der Strahlensysteme, by E. B. Cowley; Horn's Einführung in die Theorie der partiellen Differentialgleichungen, by A. R. Crathorne; Forsyth's Lehrbuch der Differentialgleichungen und Poincaré's Calcul des Probabilités, by R. D. Carmichael; Lamb's Dynamical Theory of Sound, by E. B. Wilson; "Notes"; and "New Publications."

# THE DIAGRAMS IN PROFESSOR THORNDIKE'S ADDRESS ON EDUCATIONAL DIAGNOSIS

THROUGH a misunderstanding the lettering was not given for the diagrams in Professor Thorndike's vice-presidential address before the American Association for the Advancement of Science, printed in *SCIENCE* for January 24. They are here reproduced with the inscriptions.

FIG. 4. The median expectation of length of stay in the New York City high schools, in the case of pupils who reported, at entrance to high schools, as shown at the left of the diagram, choice of occupation and intended length of stay.

FIG. 5(a). The number of pupils, reporting themselves at entrance as expecting to complete the course, who leave in each successive year.

FIG. 5(b). The number of pupils, reporting themselves as expecting *not* to complete the course, who leave in each successive year.

FIG. 6. The median expectation of length of stay in high school for pupils according to the family's monthly expense for rental.

FIG. 7. The median expectation of length of stay in high school of pupils who during the first term were rated by their teachers as shown at the left of the diagram.

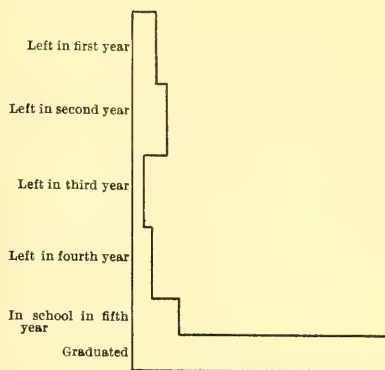

FIG. 8(a). The number of pupils, ranked in the top tenth for ability, who leave in each successive year.

FIG. 8(b). The number of pupils, ranked in the bottom tenth for ability, who leave in each successive year.

### SPECIAL ARTICLES

#### A WILD HOST-PLANT OF THE BOLL-WEEVIL IN ARIZONA

As cultivated cotton is the only plant thus far known to harbor the boll-weevil, the existence of another host-plant of these destructive insects may be worthy of notice. The plant

in question is not very well known, even from the botanical standpoint. It was described from Sonora by Asa Gray in 1855 as *Thurberia thespesioides*, and has also been identified with another Mexican species published in 1824 under the name *Ingenhouszia triloba*. But this generic name was preoccupied, an East Indian plant of another family having been named in honor of Ingenhousz in 1818. Nor is it certain that the Mexican *Ingenhouszia triloba* represented the same species that grows in Arizona. The flowers of the latter are white, while those of the Mexican species are described as yellow.

It is true that the characters supposed by Gray and Bentham to be of generic importance do not serve to distinguish *Thurberia* from *Gossypium*. The cells of the capsule show the same numbers, 3 or 4, as in many kinds of cotton, and some kinds of cotton imitate *Thurberia* in having a row of hairs on the inside of the carpel. But *Thurberia* offers more essential differences in the simple involucre bracts, the expanded corolla, and the absence of lint from the seeds, which are covered only with a thin, short fuzz. In view of these facts Gray's name may be retained.

Some attention has been given to *Thurberia* for the last three or four years in connection with the cotton-breeding work of the Department of Agriculture, because it seemed to be the nearest relative of the genus *Gossypium*. In external appearance and general behavior it is closely similar to some of the shrubby perennial types of cotton. The leaves are narrow and deeply divided like those of the so-called "okra" varieties of Upland cotton.

Until the present season the study of *Thurberia* has been limited to greenhouse and garden plants. The desirability of observing the habits and variations of the species in the wild state has been recognized, but all the localities where the plant was formerly known to exist were rather inaccessible. New localities on the slopes of the Santa Catalina Mountains not far from Tucson, Arizona, have been discovered recently by Professors Geo. F. Freeman and J. J. Thornber, of the University of Arizona, and one of these localities was visited a few weeks ago through the courtesy of Mr.

Harold Bell Wright, who is a collaborator in the breeding work of the Bureau of Plant Industry. In a small canyon about two dozen large shrubby plants of *Thurberia* were found. Some of them might even be described as small trees, attaining a height of 10 feet, with hard woody trunks an inch in diameter. Six definite rings of annual growth are shown on one specimen.

The presence of punctures like those made by the boll-weevil on some of the seed capsules led to further search for the cause of the injury. At first only a few larvæ or pupæ could be found, embedded among the seeds of the nearly mature capsules, but finally a capsule containing an adult weevil was discovered by Mr. Wright. As all the plants had passed the flowering stage there was no means of learning whether the insect breeds in the floral buds as well as in the seed capsules, but it seems to be a habit of *Thurberia* to flower and fruit for only a short time in September and October. This habit of fruiting would not allow more than one or two broods of weevils to develop in each season.

Cotton is much more susceptible to weevil injury because it produces buds and bolls through a much longer period, thus providing facilities for breeding several generations of weevils. The fact that *Thurberia* is so much better adapted to escape serious injury may mean that it is the original host of the boll-weevil. Otherwise the infestation of *Thurberia* at Tucson must be explained by reference to prehistoric cotton cultures, which might have brought the weevil in from Mexico. The Pima Indians of Central Arizona cultivated an indigenous variety of cotton until a few decades ago, and the Hopi Indians of New Mexico still raise a little of their native cotton for ceremonial purposes. That the weevils in the Santa Catalina Mountains represent a recent importation from Texas seems altogether improbable.

As no cotton is now grown in the region of Tucson, the existence of weevils in the wild *Thurberia* is of no direct agricultural interest. But it is obviously desirable to know more of the habits and distribution of *Thurberia* in Arizona and adjacent states. A rapid exten-

sion of cotton culture is now going on in the Salt River Valley and other irrigated districts of Arizona and may bring the crop within the range of the native weevils.

O. F. COOK

BUREAU OF PLANT INDUSTRY,  
U. S. DEPARTMENT OF AGRICULTURE,  
December 18, 1912

### THE AMERICAN SOCIETY OF ZOOLOGISTS

THE Eastern and Central Branches of the American Society of Zoologists met in joint session at Western Reserve University, Cleveland, Ohio, December 30 and 31, 1912, and January 1, 1913, in conjunction with the American Association for the Advancement of Science and the American Society of Naturalists.

The following officers of the Eastern Branch were elected for the year 1913:

*President*—Raymond Pearl, Maine Agricultural Experiment Station, Orono, Me.

*Vice-president*—Alexander Petrunkevitch, Yale University, New Haven, Conn.

*Secretary-treasurer*—Caswell Grave, Johns Hopkins University, Baltimore, Md.

*Additional Member of the Executive Committee*—C. E. McClung University of Pennsylvania, Philadelphia, Pa.

These officers, in addition to R. G. Harrison (elected at the Ithaca meeting in 1910) and H. E. Jordan (elected at the Princeton meeting in 1911), will constitute the executive committee of the Eastern Branch for the ensuing year.

The present officers of the Central Branch continue until the next meeting of this branch.

The president of the society as a whole until the next joint meeting is Henry B. Ward, University of Illinois, Urbana, Ill.

The following persons were elected to membership in the American Society of Zoologists:

Eastern Branch—Ethel N. Browne, Princeton University; Esther F. Byrnes, Brooklyn High School for Girls; Wayland M. Chester; C. G. Crampton, Massachusetts Agricultural College; Edward C. Day; Alfred O. Gross, Bowdoin College; E. Newton Harvey, Princeton University; Davenport Hooker, Yale University; Otto F. Kampmeier, University of Pittsburgh; Henry Laurens, Yale University; Samuel C. Palmer; Edward E. Wildman, West Philadelphia High School.

Central Branch—Alexander MacGillivray, Cornell University; Gideon S. Dodds, University of

Missouri; George A. Baitzell, Central College; W. C. Allee, University of Illinois; Aute Richards, University of Texas; Bertram G. Smith, State Normal School, Ypsilanti, Mich.; William Scott, University of Indiana; W. A. Willard, University of Nebraska; Addison Gulick, University of Missouri; Robert K. Nabours, Kansas Agricultural College; Mary T. Harmon, Kansas Agricultural College.

Elected to honorary membership, in recognition of his services to American zoology, Honorable James Bryce, British Ambassador to the United States.

Professor Nutting reported that the committee on zoological nomenclature, appointed by the Central Branch at its last meeting, had published its report in *SCIENCE*, December 13, 1912. The report was approved.

Professor S. A. Williston was elected a delegate at large to the Eighth International Zoological Congress at Monaco and requested to present the above report to the congress. The executive committee of the society was authorized to appoint an alternate.

The report of the treasurer of the Eastern Branch was presented as follows:

#### Receipts

##### Investments:

From Raymond Pearl, Certificate of Stock No. 11,865 Industrial Savings and Loan Co .....	\$150.00
--	----------

##### Current funds:

Received from R. Pearl .....	195.41
Interest on current funds .....	2.18
Dividend from stock .....	3.75
Dues from members .....	187.00
From treasurer Central Branch, for share of printing members' list ....	18.95
Total receipts in current funds .....	\$407.29

#### Disbursements

Smoker, Princeton meeting .....	\$7.00
Express on records from Orono, Me. ....	1.15
Postage and envelopes .....	15.90
Membership cards and receipt book ....	2.75
300 copies list of members (\$45.00) with envelopes .....	46.35
Clerical assistance .....	5.98
Fees of notary and clerk of court .....	.77
Secretary's ticket, Hanover to Cleveland .	36.10
Total disbursements .....	\$116.00

Total receipts, as above .....	\$407.29
Deduct total disbursements .....	116.00
Balance in current funds .....	\$291.29

The report was approved by an auditing committee and accepted by the society.

The treasurer reported the failure of the Industrial Savings and Loan Co. in which the permanent funds of the Eastern Branch had been invested by a former secretary-treasurer. The treasurer, Professor J. H. Gerould, was appointed custodian of the claim on the fund so invested in order that legal processes incident to the change of treasurers might be avoided.<sup>1</sup>

Mr. Mayer offered resolutions upon the deaths of Professors T. H. Montgomery and Nettie Stevens. These were adopted by the society and the secretary instructed to publish them in *SCIENCE* and transmit copies to the families of the deceased members.

The society passed the following resolution by unanimous vote:

WHEREAS: It is essential to the advancement of the interests of American fisheries both at home and abroad that the commissioner of fisheries should be a man of the highest scientific attainments, as well as one of wide practical experience in the varied activities of the Bureau; therefore,

*Be it Resolved*, That the American Society of Zoologists, in session at Cleveland, Ohio, without expressing preference for any particular candidate, earnestly urge upon the President-elect, in the event that a change be made in the administration of the United States Bureau of Fisheries, the selection of a person for this office who is recognized as a trained zoologist, who has shown marked ability in the practical application of zoological methods and results, who is thoroughly familiar with the problems of American fisheries, and who possesses the ability so to organize and administer the affairs of the bureau as to bring the efficiency of its work to the highest development.

<sup>1</sup> At a meeting of the executive committee it was resolved that the funds of the society should for the present be invested only in savings banks or other institutions recognized as suitable depositories for trust funds and that the treasurers of the two branches should confer during the coming year and present recommendations for the investment of the society's funds not held for current expenses.

A committee consisting of E. G. Conklin (chairman), H. V. Wilson and A. G. Mayer was appointed to present this resolution to the President-elect.

After consideration and discussion of a motion by Professor C. C. Adams, the society voted to give the officers power to act for them in the support of both state and national legislation looking toward the protection and conservation of wild animals.

The following papers were presented at the meeting, either in full or by title:

#### ECOLOGY AND BEHAVIOR

A. S. PEARSE (University of Wisconsin): *The Beaches at Nahant, Mass.*

S. R. WILLIAMS (Miami University): *Notes on the Distribution of Thermobia domestica and Lepisma saccharina.*

These two *Thysanurans* are common in the house in Oxford in which I live, *Thermobia* in the attic and *Lepisma* in the cellar. The conditions of moisture and temperature are of course very different at the two levels. Daily records from July 11 to September 11, our hottest weather, gave the following results:

*Cellar*.—Highest record of maximum thermometer, 27° C., July 15. Lowest record of the minimum thermometer, 17° C., August 6. Average for two months, maximum, 22.7°; minimum, 19.5°.

*Attic*.—Highest record of maximum thermometer, 41° C., July 14. Lowest record of minimum thermometer, 11.5° C., August 4 and 5. Average for two months, maximum, 33.9°; minimum, 20.7°.

Animals of both species were kept in jars in the attic. It was found that when the temperature reached 40° C. or more, as it did July 14, 15, 24 and September 3, the *Lepisma* died, the last to succumb being young which hatched from eggs laid in the jars. To test this experimentally some *Lepisma* and *Thermobia* were heated over a water-bath in a flask with a thermometer passing through the cork. It is difficult to keep the animals from burning to death on the hot glass of the flask but an insulating material was put in the flask. All *Lepismas* died while the air-temperature of the flask was not beyond 40° to 43° C., while *Thermobia*—known in England as the "fire-brat"—died at 47° to 48°. This indicates experimentally that *Lepisma* is unable to withstand the heat of an average summer in an attic at our latitude and hence does not go there, while *Ther-*

*mobia* endures such heat easily. The arrangement of the scales on the two forms is likely a part of the explanation of the distribution, since they lie flatter and less loosely on *Lepisma* than they do on *Thermobia*. Further observations are being carried on with reference to the moisture relations of the two forms in these habitats.

V. E. SHELFORD (University of Chicago): *An Experimental Study of the Reactions of certain Animals to Gradients of Evaporating Power of Air*. (Lantern.)

Millipedes, ground beetles and amphibians inhabiting moist forests react negatively, usually by turning back, when they encounter air of high evaporating power. The negative reaction usually begins after several trials of the air of high evaporating power. The reactions are similar when the evaporating power is due to current and when due to dryness, but in some cases they are more pronounced when it is due to higher temperature. Comparable animals from habitats where evaporation is great do not react sharply to the gradients used with the forest animals. Sharpness of reaction is not correlated with the length of time required to kill the animals with dry air.

J. W. SCOTT (Kansas Agricultural College): *The Viability of certain Cystocerci in Pigs and in Young Dogs*.

A series of experiments was tried to determine whether hogs are injured by feeding upon rabbits that are infected with the cysticerci of *T. serrata* and *T. serialis*. When corn is scarce it is a common practise for farmers in the western part of Kansas to feed jackrabbits to their hogs instead of corn. The intermediate host of *T. serrata* is the cottontail or common wild rabbit, but this parasite is occasionally found in the jackrabbit. In the vicinity of Manhattan out of a total of sixty-one rabbits examined during the winter of 1911-12, fifty-one (nearly 84 per cent.) were infected with cysticerci of *T. serrata*. The multiple cyst of *T. serialis* is found occasionally in the cottontail but is very common in the jackrabbit. This cyst may grow as large as a goose egg, and a single jackrabbit may have as many as half a dozen or more of these so-called "waterblisters" in various stages of development. Cysticerci from both species of tapeworms were fed to pigs weighing from seventy-five to ninety pounds, care being taken to prevent injury to the cysts before they were swallowed. Though a large number of cysticerci were fed, not a single tapeworm was found

when the pigs were killed ten days later. When the same kinds of cysticerci were fed to young dogs from 90 per cent. to 100 per cent. were recovered in the form of young tapeworms. These experiments indicate a very high degree of specialization of the parasite with reference to its optimum environment.

A full account of these experiments, together with the time required for transformation, rate of development and effect upon the definitive host, will be published later.

C. C. ADAMS (University of Illinois): *Ecological Surveys*.

R. H. WILCOTT (University of Nebraska): (1) *Some Aspects of Faunal Conditions in Western Nebraska*. (Lantern.) (2) *Biological Work in the Alkali Lakes of Cherry County, Neb.*

F. B. ISELY (Central College) (introduced by W. C. CURTIS): *Experimental Study of the Growth and Migration of Fresh-water Mussels*.

About 900 specimens, representing eleven species, of fresh-water mussels were tagged, weighed, measured, initial records taken and planted (returned to the stream or pond) by the writer in June, 1910. Many of these specimens were reclaimed, a number of times, and further records taken in 1910, 1911, 1912. Tabular results concerning the growth and migration of 122 of the specimens under observation are given.

A few points from the summary may be stated as follows:

1. Rate of growth is exceedingly variable.
2. The summer months are the growth months.
3. Lines of arrested growth may be called *rest rings*, the conspicuous ones being usually winter rest rings; occasionally, the rest rings may be two or more years apart, more often, however, several equally prominent rings may be formed in one year. Prominent rest rings are generally due to double prismatic and epidermal layers.
4. Under favorable environmental conditions there is little migration, especially among the *Quadrulæ*.

J. E. WODSEDALEK (introduced by A. S. PEARSE): *Some Results of Studies on Behavior and Starvation of Dermestidae*.

NATHAN FASTEN and GEORGE WAGNER (University of Wisconsin): *The Behavior of a Parasitic Copepod, Lernaeopoda edwardsii*.

This copepod is exclusively parasitic on the brook trout (*Salvelinus fontinalis*). During its free-swimming existence, not more than two days

at the most, it is strongly positive to intense illumination, whereas in light of low intensity it remains indifferent. On that account the copepod swims about close to the surface of the water throughout most of the day, with a spiral, dart-like motion, which in many respects is similar to the locomotion of the hunter ciliates. At night it sinks to deeper regions, due to its high specific gravity. These migrations are parallel with those of the brook trout and are, therefore, of great advantage to the life of the parasite. Increasing the temperature of the water, even to a degree that proves fatal, does not alter the reaction of the copepod to light. Chemicals also, such as sodium chloride, potassium chlorate, copper sulphate, calcium chloride, hydrochloric, sulphuric, tartaric and oxalic acids cause no reversal in the behavior of the copepod to light. In hydrogen-peroxide, magnesium sulphate, nitric and acetic acids indications of reversal were noticeable. The copepod reacts quickly to pieces of gill of the brook trout, but not at all to those of rainbow trout.

#### COMPARATIVE ANATOMY

ALEXANDER PETRUNKEVITCH (Yale University): *The Origin of Arachnida in the Light of Paleontological Evidence.*

EDWIN LINTON (Washington and Jefferson College): *Note on a Viviparous Distome.*

A distome (species not yet determined) found in the cloaca of a herring gull at Woods Hole, Mass., July 22, 1912, is unique in that the folds of the uterus contain ova in which active, ciliated larvæ (miracidia) have developed. The larvæ are conspicuous on account of the black pigment eyespots. When the larvæ are set free from the parent worm each is seen to contain a single well-developed redia.

So far as the early stages of distomes have been observed in the marine invertebrates of the Woods Hole region they show a much less complicated life-history than that of the liver fluke. Sporocysts have been found (in certain mollusks and one annelid) some containing tailed, others tailless cercariæ. None were seen with rediæ. In those cases the redia stage is missing. In this distome from the herring gull the sporocyst stage is evidently omitted.

J. F. ABBOTT (Washington University): *Adaptations for Air-breathing in the Ocyrod Crabs.*

F. D. BARKER (University of Nebraska): *A Contribution to the Parasitic Turbellaria.* (Lantern slides and demonstrations.)

While working on the parasites of the fishes at the Bermuda Biological Station last summer two new species of parasitic turbellaria were found in the posterior sacculated portion of the intestine of the Bermudian holothurian *Stichopus*, both the black and the spotted varieties harboring the parasites.

In Bronn's "Klassen und Ordnungen des Thier-Reichs," 1908: 2574, forty-seven parasitic turbellaria are enumerated. These are classed as ecto- and ento-"Raumparasiten" and ecto- and ento-parasites; the latter are further divided into cœlomic, liver, kidney and intestinal parasites.

Parasitic turbellaria have been found in the following hosts: annelids, gephyreans, crustaceans, echinoids, holothurians, lamellibranchs and gastropods. Six species representing two genera have been reported for holothurians in general and one species, *Anoplodium schneideri*, has been described by Semper as occurring in the intestine of the holothurian *Stichopus variegatus*. With the exception of two species, the parasitic turbellaria of the holothurians occur in the body cavity. Not all of the holothurians examined were infected and in no case was the infection severe, twelve parasites being the largest number found in any one host. Both species of turbellaria were found in only one third of the animals examined, the larger elongated parasite being the more abundant.

The preliminary study of these turbellaria and a comparison with the known parasitic turbellaria shows them to be new and undescribed species and thus adds two more parasitic turbellaria to the list.

The detailed description of these forms will be published soon and will be followed by a further study of the histology and life history of these turbellaria with the hope of settling or giving new light and additional knowledge on a number of points concerning trematode and turbellarian morphology and histology which are now in dispute.

H. S. PRATT (Haverford College): *The Trematode Parasites of the Loggerhead Turtle.*

The parasites of the loggerhead turtle (*Caretta caretta*) have been studied from the Mediterranean Sea and the Gulf of Mexico. The two principal localities in the Mediterranean region where they have been collected are Trieste and Alexandria, where a large number of the turtles have been investigated for parasites by well-known zoologists from the time of Rudolphi to the present. In the most recent times Braun and

Looss have been the most active in this field. In the Gulf of Mexico three turtles have been investigated by Professor E. Linton and two by myself at the laboratory of the Carnegie Institution of Washington situated on Dry Tortugas. In all, nineteen species of trematodes have been found. Of these, nine species occurred in the turtles of the Gulf of Mexico, of which eight species live also in those of the Mediterranean Sea, only one species being peculiar to the former locality. Ten species which occur in the Mediterranean have not yet been obtained in the Gulf of Mexico, although the probability that some of them at least will be discovered there when a larger number of loggerheads are investigated is a strong one.

The most numerous trematode occurring in the Gulf of Mexico loggerheads is *Cymatocarpus undulatus*, several thousands of this species having been found in the duodenum of each of the five turtles investigated. This worm is apparently not common in the Mediterranean, not having been found at all off the Italian coast, although it has been taken a number of times at Alexandria. Among the individuals of this species in the duodenum of two of the turtles were many specimens of *Rhytidodes gelatinosus*, and in the intestine of two turtles was *Pachysolus ovalis* many worms being present in one case and but two in the other. This last-named worm is the only species which is peculiar to the Gulf of Mexico, but its similarity to *P.irroratus* of the Mediterranean is so great that it is a question if it is not identical with it. The urinary bladder and rectum of two turtles contained many specimens of *Plesiochorus cymbiformis* and in the intestine of one turtle were two specimens of *Monostomum pandum*, while in another was found a single *Cricocephalus delitescens*. *Orchidasmus amphiorchis*, which is a very common worm in the Mediterranean, was found in only one turtle, and then in small numbers.

Further discussions of these trematodes with descriptions of those which are as yet insufficiently known will be published in the *Archives de Parasitologie*.

J. W. SCOTT (Kansas Agricultural College): *Note Concerning the Origin of the Introvert in Cirratulus*.

R. M. STRONG (University of Chicago): *Further Observations on the Olfactory Organs of Birds*.

In a study of the olfactory organs of birds, I found that the fulmar has very large olfactory lobes which are in immediate contact at their anterior ends with the posterior ends of the nasal

chambers. There are no so-called olfactory nerves.<sup>2</sup> Since the paper which described that condition was published I have studied the olfactory organs of a number of species of the order to which the fulmar belongs, *i. e.*, the Tubinares. In all of these species similar conditions prevail, though the relative size and form of the olfactory lobes varies. The anterior turbinal is small in the Tubinares, but the other two turbinals are well developed. The posterior turbinal, to which most of the olfactory epithelium is apparently confined, is relatively large, especially in the storm petrels. The results of this work will be published later in connection with a study of the anatomy of the Tubinares.

A. W. MEYER (Stanford University): *Degenerative and Obliterative Changes in the Fetal Vessels and Ligaments*.

The observations which I desire to report were made quite incidentally in connection with other investigations. Hence in spite of the fact that a rather large series of animals were examined, they should not be considered as being exhaustive. The first matter of some interest in connection with these fetal structures is the entire absence of a ligamentum teretis hepatis and a ligamentum suspensorium hepatis in *Canis familiaris* and *Ovis aries* and probably also in bovines. In view of current descriptions and conceptions this seemed a rather surprising fact and I was further surprised that the statement also holds for old specimens of *Felis domestica* and *Cavia cabaya*, although in them the complete disappearance of these structures is comparatively slower. In *Canis familiaris* and *Ovis aries* both the vena umbilicalis and the ligamentum suspensorium hepatis disappear by the end of the second or third month of fetal life, as a rule, but they persist much longer in the other animals mentioned.

Since the umbilical vein disappears so early in both the dog and sheep it would of course be incorrect to say that a ligamentum teres was ever formed or existed in them. On the other hand, in cats, rabbits, guinea pigs, rats, etc., in which the degeneration is much slower and where it may be partial, a more or less temporary round hepatic ligament may hence be formed.

In the dog and the sheep the degeneration and regression of the umbilical vein and suspensory ligament of the liver take place *pari passu* as a rule, and they may even be somewhat interdependent or at least inter-related processes.

<sup>2</sup> See Strong, 1911, *Jr. Morph.*, Vol. 22, No. 3, pp. 619-660.

Moreover, the distal extremity of the degenerating umbilical vein after being freed from the abdominal wall may obtain a secondary attachment as a result of the formation of adhesions, to the parietal peritoneum usually somewhat more cranial to the umbilicus; to the liver or gall bladder; or most commonly to the extensive fold of extra-peritoneal fat lying ventrally in the median line between the processus xiphoideus and the umbilicus. Besides, such secondary attachments—which are, of course, purely temporary—may nevertheless retard the progress of the degenerative changes in the umbilical and omphalo mesenteric veins considerably. This is especially well illustrated in case of the omphalo mesenteric veins of the cat which are not rarely present still in cats one to two years old because they have come into more or less permanent relations to, and function as part of the systemic venous system. This rather surprising fact was especially well illustrated in two cats in which one of the omphalo mesenteric veins had obtained a secondary attachment to the apex of the bladder and arose in several vesicle veins. In these cases the omphalo mesenteric vein was patent throughout, filled with blood which could be forced into the superior mesenteric vein very easily by pressure and which was later expelled spontaneously by contraction in response to cooling of the vessels after death. A similar phenomenon was noticed in case of the umbilical vein of the cat, the distal degenerated and retracted extremity of which obtained a similar connection with the extra-peritoneal veins of the ventral body wall. It is evident, of course, that the establishment of such secondary vascular connections on part of the umbilical vein might and does materially affect the rate of regression, not only of the vein itself, but of the suspensory ligament as well. This is particularly true if, as is not infrequently the case in cats, a very large lymphatic vessel lying between the layers of the suspensory ligament extends parallel to its concave and free caudal border.

The extremely late disappearance of the omphalo mesenteric vessels in the cat not uncommonly observed is as remarkable as the early disappearance of the umbilical vein in the dog and sheep. Indeed it is not rare to find the omphalo mesenteric vessels persisting as fine fibrous strands which may contain no remnant of the lumen and which have obtained a secondary attachment elsewhere, in cats half a year to a year old.

The umbilical arteries which retract intra-ab-

dominally instantaneously at the time of rupture of the cord in *Bos taurus* and *Ovis aries* were never found to have secured such a secondary attachment, but in *Canis familiaris*, *Felis domestica*, *Lepus cuniculus*, *Mus rattus* and *Cavia cobaya*, in which they remain attached to the abdominal wall at the umbilicus and become detached only one to two weeks *post natum*, their free ends obtain a firm secondary attachment to the apex of the bladder in the majority of cases. Yet they were never observed to come into relation to the systemic arterial system with their free ends or their degenerating trunks.

The early complete disappearance of the umbilical vein of the dog and sheep was due to a degeneration of its musculature and consequent absorption. These degenerative processes which in these animals were sometimes accompanied by a certain amount of connective tissue invasion never ended in the formation of a truly ligamentous structure, however. In the cat, rabbit and guinea-pig, on the contrary, such a transformation into connective tissue of at least the distal portion of the umbilical vein was not uncommon.

In case of the umbilical arteries in any of these animals two methods of transformation were observed. The connective tissue which displaced the musculature arose either of subintimal or adventitial origin. In the first case it formed between the intima and the elastica interna when present, which was usually the case, while in the second case it displaced and invaded the media from without. However, since there is a great deal of connective tissue between the fasciuli and concentric layers of muscle fibers of fetal vessels, both these processes may also be accompanied by proliferation of the inter-fascicular, intra-medial connective tissue. Moreover, it is evident that these processes may all be combined. Nevertheless, this was usually not the case and instances were observed in which the musculature was plainly degenerating and being displaced only from within, for the outer layers were well preserved, while in other cases exactly the opposite conditions were present.

No evidence whatever for the origin of connective tissue from endothelium was obtained and the initiation of degeneration and transformation were apparently independent of thrombus formation, but apparently not of the presence of non-coagulated blood in the lumen of the vessel.

L. B. WALTON (Kenyon College): *The Anatomy of the North American Land Planarians.*

A. M. REESE (West Virginia University): *The Histology of the Enteron of the Alligator while Hibernating and while Feeding.*

The chief object of this investigation was to determine the effect of hibernation upon the digestive tract of the alligator, and incidentally to study the histology of these structures, which has not, so far as the author is aware, been done before in any detail.

The material used was taken from young animals at the end of a feeding period of about five months, and towards the end of the hibernating period after fasting for four or five months.

The regions of the enteron that were studied were as follows: the tip and base of the tongue; the anterior and posterior regions of the roof of the mouth; the anterior and posterior regions of the esophagus; the cardiac, fundic and pyloric regions of the stomach; the anterior, middle and posterior regions of the small intestine; the anterior and posterior regions of the rectum.

Since the work was started at the end of the hibernating period the tissues of that period were studied and drawn first.

The only difference between the structure of the tip of the tongue during hibernation and during the feeding season is that the scaly epithelium with which it is covered is somewhat thicker and more compact in the former than in the latter condition, though even this difference may have been due to differences in the ages of the animals used. The base of the tongue differs from the tip in having a thicker epithelium and in having compound, tubulo-alveolar glands. These glands in the hibernating animal have many more alveoli than in the feeding animal, though this, again, may have been due to the difference in age.

The lining of the roof of the mouth is essentially the same as that of the tongue. The glands are found only in the posterior region. The slight differences in the papillæ here found may easily be due to the difference in age.

The esophagus shows the usual layers for that region. Its epithelium is partly ciliated in the anterior part. The muscularis mucosa is very scant in the anterior region. The only difference between the two stages is that in the feeding the muscularis mucosa in the anterior region is much more strongly developed than in the hibernating stage; and in the former the nuclei are not arranged in two zones as in the latter.

The stomach has the usual layers, and has essentially the same structure in the three regions studied, except that the wall in the fundic region is much the thickest, due mainly to the great thickness of the middle muscular layer. Only one kind of cell is found in the gastric glands. No difference is to be noted between the hibernating and the feeding conditions.

The chief peculiarity of the small intestine is the apparent entire absence of the submucosa. Goblet cells are also wanting. The greater diameter of the anterior region is due both to the greater diameter of the lumen and to the greater thickness of the walls. The middle and posterior regions have about the same diameter, though the mucosa becomes thinner and less complicated caudad. There is practically no difference between the hibernating and feeding stages.

The anterior and posterior regions of the rectum have essentially the same structure. No difference can be seen between the hibernating and feeding conditions.

The differences, then, between the digestive tracts of the hibernating and feeding animals are so slight that it may be said that hibernation has practically no effect upon the enteron of the alligator, at least in captivity.

F. W. CARPENTER (University of Illinois): *Methylene Blue Preparations of Nerve Endings in Cranial Autonomic Ganglia.* (Demonstration.)

H. L. BRUNER (Butler College): *Jacobson's Organ and the Respiratory Mechanism of the Urodeles.*

In the amphibians the relation between respiration and smell is complicated by the peculiar nature of the respiratory mechanism, which includes an apparatus for closing the nasal passage. In this group Jacobson's organ, when present, is a blind sack or groove opening into the general olfactory cavity. According to the theory of Seydel (1895) it is stimulated by odorous material which passes through the choana from the mouth. The organ in question has been recognized in the *Anura* and *Salamandrida* and among the lower urodeles, in *Cryptobranchus* and *Amphiuma*. It is wanting in *Proteus* and *Necturus*.

Among the amphibians studied, the organ of Jacobson is present in all forms in which the expiratory media pass through the nose in adult life. In *Necturus* and *Proteus* access to the nasal cavity from the mouth is prevented by a mechanical breathing valve at the choana and the organ

of Jacobson is wanting. Seydel assumed that this simple condition of the olfactory organ of *Necturus* is a primitive one, but it seems more probable that the organ has degenerated on account of the presence of the choanal valve.

J. F. DANIEL (University of California): *The Endoskeleton of Heterodontus francisci*.

F. D. BARKER (University of Nebraska): *The Parasites of the Muskrat*. (Lantern slides and demonstration.)

With the exception of a brief note by Leidy, 1888: 126, there is no reference to or description of the parasites of our common muskrat.

A recent examination of 27 muskrats trapped along the Loup River in Nebraska revealed a heavy parasitic infection. Over 600 worms were found, including trematodes, cestodes and nematodes. Seven species of trematodes, one species of cestode and two species of nematodes were represented.

The work on the trematodes which is now completed shows all seven species to be new and heretofore undescribed with one possible exception, and in that case there is only the meager description of Leidy referred to above.

The large number of different and new species of parasites which occur in the muskrat but emphasizes the virgin and fertile nature of the field of parasitology for the investigator and also emphasizes the need and the value of a thorough survey of the parasitic fauna of our common animals by states, or better, by smaller units of area.

The description of one of the trematode parasites of the muskrat has been published and the descriptions of the other six species will appear soon.

#### COMPARATIVE PHYSIOLOGY

MAX MORSE (Trinity College): *The Role of Phagocytosis in the Process of Involution*.

Involuting organs, such as the tail of the anouridan larva, their gills, etc., have been described by

Metchnikoff and others as atrophying through phagocytosis. Metchnikoff believed that the phagocytes arose from the muscle cells themselves, but sections through organs at the time of degeneration show no mitoses in the muscle cells. Others, such as Mercier, believe that the leucocytes act as phagocytes and cause the breaking down of the organs, but differential counts of blood from young larvæ, those during metamorphosis and from adults show no correlations which would indicate that polynuclear leucocytes, basophiles, eosinophiles, large or small mononuclear leucocytes play any rôle in the process. The process of atrophy here is similar in essential respects to the involution of the uterus in mammals, to the degeneration of the individuals of the bryozoan colony, etc., where the process is doubtless autolysis and experiments are in progress, which seem to show that this is the case in the metamorphosing amphibian larva.

H. W. RAND (Harvard University): *Reactions of the Tentacles of Sagartia lucia to Tactile Stimulation*.

The reactions of tentacles of *Sagartia lucia* to tactile stimulation vary from a minimum reaction consisting of a slight longitudinal contraction in a narrow zone at the level of the point stimulated, to a maximum contraction of the entire tentacle. Occasionally the response extends to neighboring tentacles or even involves the entire animal. In a certain animal at a certain time the degree of the response varies with the intensity of the stimulus. But in the same animal at different times, or in different animals at the same time and under similar conditions of experimentation, the reactions show great variation.

Two distinctly opposed physiological conditions were noted. In the one condition (designated as positive) the distinctive feature of the reaction is a bending of the tentacle at the point stimulated and toward the stimulated side. In this condition

the responses are, in general, like those involved in taking food. The distinctive feature of the second condition (negative) is a bending of the tentacle at the point stimulated but away from the stimulated side. The positive and negative conditions are not necessarily correlated with hunger and satiety, nor with the state of the medium in which the animal lives, nor with fatigue. While external conditions remain as nearly as possible constant, the animal may abruptly change back and forth from one condition to another. The reactions, therefore, while influenced by external conditions, depend essentially upon an internal physiological complex.

A. J. GOLDFARB (College of City of New York): *On the Effects of Changes in Density of Sea Water upon Growth and Regeneration.*

G. H. PARKER and E. M. STABLER (Harvard University): *Taste, Smell and Allied Senses.*

The statement that the stimulus for smell is material in the form of gas and for taste is material in solution is partially incorrect, for both sense organs are normally stimulated by solutions. It has been recently shown that fishes respond to their food by smell and taste much as air-breathing vertebrates do. What seems to be the chief difference between smell and taste is that the olfactory organs are stimulated by very dilute solutions, the organs of taste only by much stronger ones. To get some quantitative statement of this difference, the strength of the stimulating solution producing the minimum stimulus was determined for a substance that had both smell and taste. The substance tested was ethyl alcohol. In preliminary tests the following results were obtained. The weakest dilution that would stimulate the mucous surfaces of the mouth was a 15 mol. solution (aqueous). The weakest dilution that called forth the sweet taste when applied to the tongue was a 2 mol. solution (aqueous). The weakest dilution that could be smelled was 1/200,000 mol. (in air). Thus the olfactory apparatus responds to a dilution about 400,000 times greater than that for taste.

G. G. SCOTT (College of City of New York): *The Effect of Fresh Water upon Fundulus heteroclitus.*

It is now well established that *Fundulus heteroclitus* is found in both sea water and fresh water. The fact that few survive rapid transference from salt to fresh water while greater numbers survive gradual transference shows that we are here concerned with another application of DuBois Rey-

mond's law of stimulation. Out of a lot of ten *F. heteroclitus* transferred from salt to fresh water, the present author kept one fish alive in fresh water for sixty days. When the caudal fin is removed at the time the fishes are transferred from salt to fresh water regeneration of new caudal fin tissue takes place, although in a month's time the amount is not as great as in sea water. Of greater interest from the point of view of the mechanism of adaptation are the results of experiments in which individual records were kept of changes in weight made at a number of intervals after immersion of *Fundulus* in fresh water. In some cases all members of a lot of fishes died soon after transfer. In each case a rapid increase in weight was noted. In other cases certain individuals gain weight rapidly and die. Other individuals of the lot after an initial gain in weight follow this with slight gains and losses—the net results in these survivors being a weight less than normal at the end of the experiment. The experiment apparently illustrates the power of *Fundulus heteroclitus* to change the organization of the limiting membranes and other structures of the body to the end that the fish becomes adapted to fresh water, a medium of very low osmotic pressure as compared with sea water.

CASWELL GRAVE (Johns Hopkins University): *The Egg of Ophiura, its Yolk Content and Course of Development.*

G. T. HARGITT (Northwestern University): *The Oogenesis of Campanularian Hydroids.*

The egg cells of *Campanularia flexuosa* arise from the basal half of an ordinary epithelial cell of the endoderm, the distal half remaining an epithelial cell; or else they arise by the transformation of an entire endoderm cell in the pedicel of the gonophore. In either case the cell so produced is transformed directly into an egg cell without any divisions occurring. Since the endodermal epithelial cells from which the egg cells arise are not different from the neighboring cells which retain their epithelial function, and since the distal half of a divided cell remains in position lining the coelenteric cavity and retains its function (the proximal half forming an egg cell), there is clearly no continuity of the germ-plasm, the egg arising from a so-called somatic cell.

Coincident with the marked and rapid growth of the egg the nucleolus (which is partly chromatin) breaks up into many fragments of various sizes and shapes, and becomes highly vacuolated. At the same time there appear small granules in the cytoplasm against the membrane of the germinal vesicle, and also similar small granules are present inside the membrane; these are found to be nucleolar fragments, some of which are chromatic in character. In addition to these indications of the escape of chromatin from the germinal vesicle there are currents in the cytoplasm extending away from the nucleus, as shown by the arrangements of the cytoplasmic granules. These currents cease when the nucleolus has entirely disappeared from the nucleus through fragmentation and dissolution, and this period is also the end of the growth period of the egg. The nucleolar material which has left the nucleus goes to form the yolk spherules of the egg.

During the growth of the egg the nuclear reticulum has remained unchanged by the modifications and transformations of the nucleolar substance which has been dissolved and cast into the cytoplasm. When the nucleolus is practically all gone and the growth of the egg has ceased the chromatin of the reticulum produces the chromosomes of the polar spindle, which are ten in number. In spite of the extensive chromatin emission, coming from the dissolving nucleolus, the chromatin remaining in the nuclear reticulum is still more than is necessary for the formation of the chromosomes, and the greater part of it

escapes into the cytoplasm in the form of granules when the germinal vesicle breaks. That which is not thus scattered forms the chromosomes.

To account for the large amount of chromatin which escapes from the nucleus there must be a formation of chromatin within the nucleus during the growth period of the egg, and the nucleolus is conceived to be the place where the chromatin is produced and transformed for the different functions it has to perform. In this origin of new chromatin, and in the extreme dissipation of chromatin during and after growth, it is believed that we have strong evidence against the continuity of chromatic material, and hence of the chromosomes. The chromatin is a metabolic product changing and transforming as all other constituents of the living cell.

J. F. ABBOTT (Washington University): *The Blood Cells and their Respiratory Pigment in Thallasema.*

H. E. JORDAN (University of Virginia): *A Comparative Study of Mammalian Spermatogenesis with Special Reference to the Heterochromosomes.*

Among the forms examined, including mongoose, cat, squirrel, pig, rabbit, white mouse, sheep, horse, mule, bull and dog, heterochromosomes are lacking in the male germ-cells of the first five, and present in the remainder. The available evidence favors more the interpretation in terms of a bipartite or compound X-element than of an associated X and Y group (idiochromosomes).

In view of the fact that heterochromosomes have recently been reported in man and rat (Guyer), armadillo (Neuman and Patterson), guinea-pig (Stevens) and opossum and bat (Jordan), the evidence indicating similar elements in the above enumerated group of six common mammals would seem to warrant the conclusion that sex-chromosomes are very generally present in mammals. Universality of presence seems vitiated for the present by the fact that in another group of five mammals such elements seem unquestionably lacking. It might be assumed that such elements are actually present in the male germ-cells, but so small or labile as to elude detection by present methods, or not presenting the usual morphology of heterochromosomes during the prophase stages. The unmistakable presence, however, of a "split-accessory" in the female germ-cells (primary oocyte) of the cat, as recorded by Winiwarter and Sainmont, and the absence of

any X-element in the male, suggests very forcibly that sex-chromosomes are present in all mammals, generally in the male, exceptionally in the female. The same end would be attained, that of numerical sex-equality, whether present in the one or the other sex. If this hypothesis can be further sustained, it would seem cogently to reinforce the evidence for an essential sex-determining function of heterochromosomes. Interpreted in terms of Mendelian heredity-formule, in those mammals in which an X-element is present in the male, the female sex is homozygous, the male heterozygous. The facts would seem to fit the hypothesis that the accessory chromosome acts as a deterrent to the development of maleness; or more accurately, and in keeping with a quantitative interpretation of sex in the last analysis, the accessory with its egg-homologue (two X-elements) inhibits male sex development; the single egg-homologue in males being insufficient to counteract the male tendency, thus giving origin to male individuals.

The complete paper will appear in a Carnegie Institution publication.

A. W. MEYER (Stanford University): *Observations on Giant Cells in Hemal Nodes and Accessory Spleens.*

M. F. GUYER (University of Wisconsin): *Remarks on the "X" Element in Fowls.* (Demonstration.)

A reexamination of old material and a further study of new material from the Langshan cock abundantly confirms the original finding of an accessory chromosome which passes undivided to one pole of the spindle in the division of the primary spermatocyte. The element in question was demonstrated through the microscope to members of the society.

T. S. PAINTER (introduced by A. PETRUNKEVITCH): *Spermatogenesis in Spiders.*

A cytological difference has been found in the spermatogenesis of the dimorphic males of the jumping spider, *Mævia vittata*. The "gray variety" contains two supernumerary chromosomes which do not divide in the last spermatogonial division. During the first maturation division these bodies show a definite association for the accessory chromosome and pass with the latter to one pole of the cell at this time. For this reason these supernumeraries have been called "ctetosomes" (implying, are the property of, are associated with, some other body). During the second maturation division the accessory chromosome divides, but this could not be certainly deter-

mined for the "ctetosomes." As a result of the unequal spermatogonial division the sperm are of three types: (1) sperm which bear the accessory chromosome and "ctetosomes"; (2) sperm which bear the accessory chromosome only; (3) sperm which bear neither of these elements.

The "tufted variety" of male lacks the "ctetosomes" although a supernumerary chromosome may be present. This body shows no relation for the accessory chromosome and seems to follow no definite law of distribution. Hence it was called a "planosome" (indicating that it wandered through the cell mitoses).

"Planosomes" have been found in many families of spiders. Most abundant in *Amaurobius sylvestris*, which may carry as many as seven "planosomes" and three "ctetosomes."

The females of *Mævia vittata* carry two doses of the accessory element.

#### GENETICS

H. H. NEWMAN (University of Chicago): *Five Generations of Congenital Night-blindness in an American Family.*

During the past two years the writer, in collaboration with Miss E. L. Brown, a former student of his and a member of the affected family, has obtained data concerning 76 individuals belonging to a family connection showing a peculiar type of hereditary night-blindness. The family originated in North Carolina, but now resides in Texas. The defect is present through life and is usually, though not always, associated with myopia and strabismus. This complex of optic affections is inherited from affected men through unaffected daughters to some of the grandsons, and in no other way. Thus, as in the case of color-blindness, the character gains expression only in alternate generations. The mechanism underlying this mode of inheritance is probably closely allied to that described by E. B. Wilson as underlying the inheritance of white eyes in *Drosophila*.<sup>3</sup> According to this scheme the factor for night-blindness is contained in the X chromosome, which Guyer has described for man. Frequently associated with night-blindness, but neither sex-limited nor

<sup>3</sup> See *Journ. Morph.*, Vol. 22, No. 1, p. 96.

linked with the night-blind complex is a fairly common optic disease known as pterygium. The factor for this defect is evidently not carried by the X chromosome.

F. E. LUTZ (American Museum of Natural History): *The Offspring of Certain Wing-mutants X Normal Drosophila and Sexual Dimorphism.*

H. S. JENNINGS (Johns Hopkins University): *Bi-parental Inheritance and the Question of Sexuality, in Paramecium.*

A. M. BANTA (Station for Experimental Evolution): *Selection within Pure Lines in Daphnia.*

Conceiving that the modification of a physiological character by selection within a pure line may perhaps be more readily brought about than the molding of a structural or morphological change, if either is to be accomplished, selection within pure lines in *Daphnia* was attempted on the basis of a purely physiological character. The character chosen was the reaction time of the young daphnids under precise conditions to a definite intensity of light.

Selections were begun in 13 lines after they had been reared under laboratory conditions as pure lines, reproducing parthenogenetically, for from six to eight generations. The selections have continued through from 19 to 25 generations in the various lines with a + strain, a strain selected for greater reactiveness to light, and a — strain, selected in the reverse direction, in each pure line. Comparing corresponding + and — strains by broods there is considerable variation in the mean reaction time, the + strain sometimes having the lower reaction time, i. e., being presumably the more reactive to light, and sometimes, *though less often*, the — strain having the lower reaction time. The general trend of the results is better shown by throwing the data into larger groups. Comparing all the + strains with all the — strains by two-month periods for the whole time during which the selection has continued it has been found that during two (the first and the third) of these five two-month periods the + strains had a higher general average reaction time by an average of 12 seconds. During the other three periods (second, fourth and fifth) the — strains had a higher reaction time by an average of 43 seconds. The general average reaction time of all the individuals of all the + strains for the entire period after selection began (944 individuals) has been 386 seconds and the corresponding average for the — strains involving 1,013 individuals has been 410 seconds, 29 seconds

or 8 per cent. more than for the + strains. Compared with the + strain the average reaction time has been significantly larger (i. e.,  $2\frac{1}{2}$  or more times the probable error) in the — strain in five of the lines. In another of the lines, however, an almost equally large difference in the reverse direction occurred.

H. H. NEWMAN (University of Chicago): *On the Unique Mode of Inheritance in the Nine Banded Armadillo.*

The study of 140 female armadillos and their offspring has shown that minute personal peculiarities, such as double, half and split scutes, double and fused bands, are strongly inherited though interchangeable in their inheritance. All of the 63 mothers that show any of these peculiarities have one or more affected offspring. About half of the unaffected mothers have affected offspring, due evidently to affected fathers, since the characters are in no way sex-limited. These characters appear sometimes unilaterally, sometimes bilaterally in the mothers. When unilateral in the mother it may reappear bilaterally in some of the offspring and unilaterally in others; or it may appear in some and be entirely wanting in others of the same set of quadruplets. When the character appears unilaterally in several of the offspring it is usually distributed so as to produce mirrored image effects between pairs or between the individuals of a pair. The characters appear to have been distributed among the four fetuses by means of a series of dichotomies of some inheritance factor, which can be best conceived of as having a material and highly localized existence—in short as a Weismannian determiner. The facts may, however, be interpreted equally well, and perhaps more acceptably, by taking into account that the cells of all the fetuses are heterozygotic in origin and that the appearance of an inherited character or its failure to appear may be due to varying degrees of success in the struggle for

supremacy between maternal and paternal inheritance forces.

The development of male characters in three female birds following the removal of the ovary has been previously reported. It is the purpose of this note to present, very briefly indeed, additional data obtained from experiments made the past season on birds ranging from five to twenty weeks of age at the time of the removal of the ovary.

*Ducks.*—Fifteen females were operated on, not including a few that died as the result of the operation. In three of these cases, owing to hemorrhage, it was impossible to remove all the ovary. These three birds did not assume any male characters. In the twelve remaining cases, the birds all began to develop the male plumage, but after a short time three individuals reverted to their original type. The cause of this reversion became apparent, when, on examination, it was found that the ovaries had partially regenerated. The remaining nine individuals have continued to acquire the male's plumage, that is, as the female feathers drop out they are replaced by feathers like those of the corresponding male. In five of these last cases it has been ascertained by a second operation that the ovary was completely removed. Although in several of these cases, the transformed females are, externally at least, almost perfect replicas of the corresponding male; nevertheless, the voice remains that of the female even in those cases where the adult voice was acquired several weeks after the operation.

*Fowls.*—Operations were performed on 18 birds. Four disappeared, four are still too young to show male characters and in three cases only part of the ovary was removed. These last did not assume any male characters. In all the remaining cases but one the male habit is developing in its entirety, viz., plumage, spurs, comb and wattles. The one exception noted that reverted to the female type after a time was due, as examination showed, to the regeneration of the ovary.

Summing up all these cases in both kinds of

birds, there is a total of 24 individuals which, at the time of writing, have assumed male characters following ovariectomy.

M. A. BRANNON (University of North Dakota): *An Examination of the Conditions of Life in Devils Lake.*

This report deals with experiments in acclimatizing fish at the North Dakota Biological Station, on the shores of Devils Lake, North Dakota. The experiments extended over a period of four summer seasons. The large-mouthed black bass, the sucker, bullhead, pickerel, yellow perch, steel head trout and rainbow trout, furnished the material for the experimental work. Their ages varied from fish that were only a few months of age to those that were several years old. The Devils Lake waters are about one and two hundredths per cent. saline with the three salts, sodium sulphate, magnesium sulphate and sodium chloride, representing the major part of the saline material in the water. None of these salts, in the percentage existing in Devils Lake waters, are toxic for fish, hence it seemed probable that it was a physical rather than a chemical condition which was inhibiting the fish life which I placed in the cultures of Devils Lake water. Proceeding on that hypothesis the fish were placed in waters that very gradually changed from the chemical composition of the sweet water, from which the fish came, to the percentage of salinity of that in Devils Lake.

The factors of heat and gas composition were found very important, as shown from the readings which were determined during the progress of the experiments.

Devils Lake was the home of millions of pickerel prior to the year 1888. Carloads were shipped away regularly each week during the winters when they were so abundant.

A series of dry years caused a lowering of the level in some fresh-water lakes formerly connected with Devils Lake. This in turn was followed by the drying up of the stream connecting Devils Lake with sweet water associates. These latter had served as breeding grounds for the pickerel which came in the autumn, like the anadromous fish to the ocean. They entered water that increased gradually in salinity. Having learned that this was the history of the former occupants of the lake the experiments of the North Dakota Biological Station were directed toward repeating artificially what had occurred in nature. Results have finally been obtained which are wholly successful. Evidences for this conclusion will be submitted in the complete discussion referred to in this abstract.

SEGIUS MORGULIS (Carnegie Nutrition Laboratory): (1) *The Influence of Protracted and Intermittent Fasting upon Growth.* (2) *The Nervous System and Regeneration.*

C. C. NUTTING (University of Iowa): *Can We get Together on the Nomenclature Question?*

The present situation is unsatisfactory, and a solution is greatly to be desired.

Points on which both parties are agreed: (1) That there should be definite laws of nomenclature, including priority. (2) That there should be a commission to interpret and administer these laws.

Position held by the International Commission on Zoological Nomenclature: (1) That no exception be allowed to the priority rule. (2) That no rule shall be modified except by unanimous vote of the commission. (3) That the commission be treated with the deference due an international court.

Position held by a large number of those who voted against the priority rule: (1) That there should be a reasonable "statute of limitation" by which names long in undisputed and general use should be excepted from priority rule. (2) That there should be an application of the principles of equity in special cases. (3) That a majority of the commission should have the power to propose changes in the rules of nomenclature, and to bring such changes to a vote by the International Commission. (4) That we retain the right of free criticism of the commission without

being required to observe the etiquette supposed to govern international courts. The commission is the servant of its constituents the "common people" among the zoologists.

The present situation regarding the priority rule: (1) The commission "stands pat" in adhering to the position outlined above. (2) A majority of zoologists are opposed to the priority rule as administered. The commission has not secured the support of its constituency, and has no means of enforcing its decrees. There is a distinct tendency among working systematists to ignore the findings of the commission.

A tentative solution: (1) Adoption of a rule by which a two thirds majority of the commission can change any rule. (2) Recognition of the legal principles of (a) the statute of limitation and (b) the law of equity as applied to individual cases.

Secretary

## SOCIETIES AND ACADEMIES

### THE SOCIETY OF RESEARCH WORKERS IN EXPERIMENTAL BIOLOGY

At the meeting of this society held on December 18, 1912, at the University Club, Washington, D. C., Dr. William Salant, chief of the section of pharmacology, Bureau of Chemistry, U. S. Department of Agriculture, gave an exhaustive review of the literature on creatin and creatinine metabolism.

Especial stress was laid upon the elimination of creatin in various diseases affecting the muscles, the central nervous system and the liver.

The recent work of Mendel and his collaborators on the relation of carbohydrate metabolism to creatin, in which it was shown that a distinct relation probably exists between the formation of creatine and the amount of carbohydrates ingested, was discussed. In addition, the speaker gave a brief résumé of his own work on the influence of caffeine on creatin and creatinine elimination, pointing out that under some conditions, such as starvation, caffeine may cause a considerable increase in the output of creatine.

Other conditions affecting the elimination of creatine and creatinine such as temperature, the amount of age, the fate of ingested creatin and creatinine, and the metabolism of these substances in different animals, were dealt upon with some length.

## THE GRAMERCY ASBESTOS DRYING OVEN

This oven fills a long-felt want for a clean and substantially-constructed substitute for the ordinary copper ovens, the appearance of which, after a short time in the laboratory, make them very undesirable.

Constructed entirely of heavy asbestos wood, with exception of the base and rack for shelves. A removable sheet metal plate, which receives the heat of the burner, forms the bottom of the oven; the permanent base frame and legs are of cast iron (aluminum finish), making the oven most rigid; while the racks for the shelves, and framework of the door, are of cast aluminum, which is practically unaffected by laboratory fumes.

The chamber of the **Gramercy Asbestos Oven** is 12"x10" and is provided with perforated asbestos shelves which can be placed at any height desired. The door is fitted with an air regulator. A ring gas burner is supplied with the oven, rigidly fitted, but most easily removed when desired.

*Price net, \$16.50.*

## RECENT PUBLICATIONS OF THE BERNICE PAUAAHI BISHOP MUSEUM

### Memoirs, Vol. II, No. 4. Quarto.

The Volcanoes of Kilauea and Mauna Loa on the Island of Hawaii

By WM. T. BRIGHAM, A.M., Sc.D. A compilation of the recorded varying conditions of the volcanoes of Kilauea and Mauna Loa to the year 1909, with index. Paper cover, 220 pages, 28 plates (1 colored), 143 text figures. Price \$3.50, postage 28 cents.

### Memoirs, Vol. III. Quarto.

Ka Hana Kapa: The Making of Bark-Cloth in Hawaii

By WM. T. BRIGHAM, A.M., Sc.D. The story of the manufacture of kapa (tapa) or bark cloth in Polynesia and elsewhere, but especially in the Hawaiian Islands. A very full description of this native manufacture, illustrated extensively from specimens in American and European museums. With a portfolio of full-sized colored lithographic reproductions of tapa. Bound in paper covers, text 276 pages, with 131 figures, index and 50 half tone plates (3 colored). Loose in portfolio, 27 lithographic plates. Price \$12.50, postage, domestic 60 cents, foreign \$1.00.

A list of other publications will be forwarded on request.

BISHOP MUSEUM PRESS,  
HONOLULU, HAWAII, U.S.A.

## Carnegie Institution of Washington

*Publications* of the Institution now number over 200 volumes, the subjects comprising Archeology, Astronomy, Botany, Chemistry, Economics and Sociology, Experimental Evolution and Heredity, Engineering, Folk-Lore, Geology, History, International Law, Literature, Mathematics, Medicine, Nutrition, Philology, Physics and Zoology. Classified and descriptive lists will be sent postpaid on application.

### INDEX MEDICUS

*A Monthly Classified Record of Current Medical Literature*

This publication consists of the complete titles of books, pamphlets, theses, contributions to co-operative works and original articles in journals, transactions of medical and scientific societies, and the like, arranged under subject-headings. The titles in certain languages, as Russian, Polish, Swedish, Danish, Finnish, Hungarian, Bohemian, Roumanian, Dutch, Modern Greek, and Japanese are translated into English. A table of contents accompanies each number, and a few months after the completion of each volume an "Annual Index of Authors and Subjects" is issued. Each number presents the literature of the month named on its cover, time being allowed for the arrival of foreign journals and for assembling, classifying, and printing the material presented.

Vols. I-VI (1903-1908) are obtainable at the rate of \$5 a volume, with 60 cents additional for postage when sent to foreign countries and Vol. VII (1909) and succeeding volumes as follows:

United States, Canada, and Mexico, \$8.00. Other countries, \$8.60.

All communications should be addressed

In that most amusing and instructive dialogue, entitled "Theætetus," the author Plato makes Socrates enter into a discussion with the youth by offering help as a skillful midwife to deliver him of a true and logical answer to the puzzling question: What is knowledge? When the youth replies,

According to my present notion, he who knows perceives what he knows, and therefore I should say that knowledge is perception,

Socrates proceeds—perhaps not altogether fairly—to identify his doctrine with the celebrated saying of Protagoras. This saying is about all we know of the positive teachings of him who was esteemed to be the founder of the Sophists. The proposition as expressed in the same Dialogue runs as follows:

Man is the measure of all things; of that which is, how it is; of that which is not, how it is not.

Even in the time of Plato the Sophists had translated this proposition into the doctrine: For every person, that is true and real which appears so to him. From this doctrine it was no long step to the conclusion, that there is possible for man only a subjective and relative, not an objective and universal truth.

From the time of Protagoras to the present, the view of the nature, authority, and limits, of perception by the senses, which his celebrated *dictum* embodies, has been the chief source both of popular and of scientific and philosophical scepticism; while the resulting doctrine of the relativity of all human knowledge, in its most

<sup>1</sup> Address of the vice-president and chairman of Section H—Anthropology and Psychology—Cleveland, 1913.

essential features, is widely dominant in scientific circles at the present time. I propose, therefore, to make it the point of starting for the consideration of two problems: First, What have modern psychology and anthropology to say about this theory of sense-perception and its resulting or allied theory of knowledge? and, second, What results from the answer to the first question as bearing upon a correct view of the relations in which the work of psychology and philosophy—the study of man—stands to the work of the other positive sciences?

But before we even propose in more definite form these two problems, let us consider in a word our right to group psychology and anthropology together under the common term, "the study of man." That the two sciences have indeed some special relations as affiliated and mutually dependent and helpful branches of study, the very fact of this sectional meeting should seem to affirm. Indeed, so intimate are the relations between the two that there are points—and more than one of such points—where it is difficult to draw a line between them. If, for example, we speak of anthropology as inclusive of a wide range of sciences—physiology, ethnology, archeology, ethics, religion, "the rise of arts and science, and the history of civilization"—of which psychology is only one, we are met by the fact that psychology, too, has spread itself over the same territory, as affording feeding-ground for its insatiable appetite. Thus we have come to speak of physiological psychology, race psychology, the psychology of ethics, art and religion and of a so-called applied psychology, which undertakes to instruct teachers how to teach, doctors how to cure, lawyers how to examine witnesses, and even overwrought and neuropathic women how to

control their eccentric and pathological tendencies.

Nor can we claim that psychology, as at present studied, confines itself to the mental or subjective side of man, while anthropology deals rather with the objective and with man's place in nature. For anthropology falls short of its highest mission and most valuable opportunity, if it does not itself make a study of the spiritual evolution of the race. (I do not, of course, employ the words "spiritual evolution" with any cant or even definitely religious significance.) Both psychology and anthropology fail of using the only method of rendering themselves scientific, if they do not proceed according to the lines marked out by the conception of development. But without further remark upon this subject, we may perhaps agree upon the conclusion that the one, psychology, is, for scientific purposes, best defined as the natural history of the individual mind, or soul; and the other, anthropology, as the natural history of the race.

Even this attempt to distinguish the two, when reflected upon from the modern scientific point of view, shows all the more clearly how intimate is the relation between them. The dependence of anthropology upon psychology, as one of the sciences which it must take into the account, is pretty generally conceded. But what is not so universally acknowledged is equally true. This is the dependence of psychology upon anthropology. No individual man can fulfil the obligation of the ancient motto, "Know thyself," without something approaching a scientific knowledge of the human species of which he is a member; of the acquired or inherent instincts, tendencies, inhibitions, naïve assumptions, emotional yearnings and strivings, which make up the greater portion of the influences controlling the so-called

nature, and natural history of the self. "Know thyself" means know thyself as a man, a member of the human race. And the natural history of the individual mind or soul, can not be described, much less explained, without interpreting it all in the light of what we have learned of the natural history of the race.

These remarks may suffice as introductory to an answer—confessedly fragmentary and full of assumptions which need proofs from sources lying outside our theme—to the two questions raised above. The first of these, you will remember, was this: What have modern psychology and anthropology to say about the view which identifies knowledge with sense-perception, and about its allied theory of knowledge?

If by perception by the senses we understand the mere fact that certain sensations form groups and sequences in consciousness, which have more or less of persistence and regularity, the banter of the wise Socrates as addressed to the youthful Thætetus is not inappropriate in our own day:

I say nothing against his doctrine, that what appears to each one to be, really is to each one, but I wonder that he did not begin his great work on Truth with a declaration that a pig or a dog-faced baboon or some other strange monster which has sensation, is the measure of all things; then, when we were reverencing him as a god, he might have condescended to inform us that he was no wiser than a tadpole and did not even aspire to be a man—would not this have produced an overpowering effect? For if truth is only sensation, and one man's discernment is as good as another's, and no man has any superior right to determine whether the opinion of any other is true or false, but each man, as we have several times repeated, is to himself the sole judge, and everything that he judges is true and right, why should Protagoras himself be preferred to the place of instruction, and deserve to be well paid, and we poor ignoramuses have to go to him, if each one is the measure of his own wisdom?

Even if we say, I do not mean the sensations of a tadpole, or even of a dog-faced

baboon, but the sensations of a man, we do not establish in perception by the senses alone a ground for science. The only way we can know what the baboon actually sees, or otherwise perceives through *his* senses, is by the use of *our* powers of perception as applied to the behavior of the baboon. Our claim to superiority over the baboon, even if we are descended from him in more or less direct line, is based upon the confidence that our perceptions, as forming a ground for a scientific knowledge of things, and perhaps for a theory of the universe, are more trustworthy and comprehensive than are his. The old-fashioned way of putting this truth was not so bad after all: Man may be an animal; indeed, he undoubtedly is an animal; but man is a *rational* animal.

Psychology, with its recent more subtle analyses, as made possible by the experimental method, has made it perfectly clear that sense-perception in the case of the human individual is an exceedingly complex development, involving all man's natural and acquired capacities and forms of functioning. Into every act of the senses which gives us intimations, or assured knowledge, of real existences and actual happenings, there enter many instinctive or acquired faiths, leaps to judgment or more slowly formed inferences, emotional factors expressive of doubt, or certainty, or negation, habits favoring or prejudiced against this or that conclusion, fleeting or more fixed associated images of memory or of fancy, and formal or regulating principles, the so-called categories or "innate ideas" of the earlier philosophy. But above all, if the process of sense-perception terminates in conviction of the reality of the object perceived, or the actuality of the event observed, then this object, or those things concerned in the event, are made the centers of forces that justify us in

giving them a place in a world outside of our own conscious selves. In other words: They are endowed with a will of their own, a will that wills not as we will. That all this is a species of the personifying of things, I have myself no manner of doubt.

But the knowledge of things as gained by the senses in the case of every individual, can not separate itself from the knowledge gained in the same way by the race of which the individual is a member. The motor reactions underlying the faiths and assumptions, the accumulated contributions of the faculties of memory and imagination, as all these are incorporated into the central nervous system, are matters of the development of the race. What even the average school-boy sees and hears, as well as thinks about and reads into his experience with the senses, is not precisely the same as that of the boy in ancient Egypt or Greece, or even the boy among the savage tribes of our own day. Are not the sense-perceptions of the believer in spiritualistic phenomena and in Christian science different from those of the sceptic and disbeliever, to-day, even when we place them in as nearly as possible identical relations to the object to be perceived? Here, then, is where anthropology becomes a valuable adjunct to any theory of sense-perception.

As to the theory of the relativity of all knowledge as stimulated by and embodied in the maxim that man is the measure of all things, its falsity or truthfulness depends entirely upon what is meant by the word "relativity." In the *Theætetus* Plato makes Protagoras—we do not know with what right—base his doctrine on the philosophy of Heraclitus. Now, no other philosopher of antiquity has been of late so re-habilitated in reputation and so clothed with honor as has the Ephesian Heraclitus. He was the founder of nat-

ural philosophy among the Greeks, the leader of the physcists of the fifth century B.C.

So powerfully impressed was he with the ceaseless change of things, the transitoriness of all the particular, that he sees in it the most universal law of the world, and can only regard the cosmos as being involved in continual change, and transposed into perpetually new shapes. All things are in constant flux; nothing has permanence.

If by the relativity of knowledge, as established by the psychological and anthropological study of man, we mean that no other knowledge is possible for human beings than that which comes into relation with human faculties for knowledge, there can be no objection to, or denial of, so obvious a truth. All man's knowledge of mankind and of the rest of the world is *human* knowledge and comes under the limitations and conditions of all human knowledge. Man's fields of knowledge have boundaries; and what he wins from these must be by patient and skillful using of the means of culture, his own senses and intellect applied to the data of his own experience.

If by the relativity of knowledge we mean also to assert that all knowing is an actual relating, an exercise of the function of relating activity, and that all things known are known as related to other things, we are only stating undoubted psychological facts. These facts are of fundamental importance in our interpretation of the true meaning of the saying, "Man is the measure of all things." Still further, if we mean that all advance in knowledge, on the part of the individual and of the race, is related to the past stages and achievements of knowing faculty, then, too, we are stating a truth on which psychology and anthropology may cordially unite. But when by the relativity of all knowledge it is meant to imply a complete distrust of

man's ability to discover and prove anything about the reality of the world in which he lives, or to apprehend with assurance of conviction what is now actually taking place within or without, or what has actually taken place in the past, we press our scepticism and its resulting agnosticism far beyond the limits warranted by a proper understanding of the Protagorean maxim. Man is indeed the measure of all things, *i. e.*, so far as things really exist for him or actually happen in the real world which environs his existence.

So, then, he who takes his attitude toward his own science, or toward the practical life, from that study of man in which psychology and anthropology may cheerfully concur, will undoubtedly hold to a certain theory of the relativity of all knowledge. This theory will lead him to say: There are a few things of which I have perfectly certain and absolutely sure knowledge. There are some more—perhaps, many more—of which I am reasonably sure; and the surer, the more I grow in knowledge. There are yet more of which I am in doubt, and about which I am holding my mind in suspense and open to the conviction which follows upon trustworthy and sufficient evidence. But the things I do not know are like a vast and limitless sea—to borrow an illustration from the philosophy of Kant—on the bosom of which lies my little island of knowledge and opinion. How far future explorers in all branches of science may sail that boundless ocean, or what other islands they may discover or treasures bring up from its depths, I am not going dogmatically to pronounce. That would be to assume more, in view of our present relations to the past and the future of science, than any one is justified in assuming. Besides as a student of man from the anthropological point

of view, I am taught to be cautiously agnostic in this regard.

But when any one says of himself, I know absolutely nothing about myself, or about things, or about the transactions between myself and things, or among things, which I am confident have a corresponding reality, he appears more modest with reference to his own powers than the doctrine of the relativity of knowledge requires that he should be. And when he goes on to say, You, too, know nothing, and can know nothing as to what is real and actual, he is not altogether polite, not to say flattering, toward a fellow aspirant for knowledge. But when he proceeds with the declaration: Neither I, nor you, nor anybody, really knows anything, or ever can know anything, about the real world and about the events assumed actually to occur in this world, his agnosticism has indeed taken a suicidal turn. For, surely such an agnostic knows that he does not know, and yet somehow exists in a world about which he and all others are in this state of perpetual and incurable ignorance; and this would seem to imply that I and others without number, in the most important respects like him, do also exist in an unknowable but undoubtedly actually existent world. It seems then that the complete agnostic is the man who is very sure that he can vindicate his agnosticism by appeal to some actual, objective standard of judgment which he and others possess in common. That is to say, while arguing from his doctrine that man is the measure of all things to the conclusion that no knowledge is possible, he involves the other very important conclusion or assumption that the world is full of actually existent rational beings, besides and outside of himself.

The importance of considerations like those just announced is greatly increased

when we apply them to the relations in which the study of man stands to that kind of knowledge which is embodied in the so-called positive sciences. The term science is properly applied to any grouping of knowledges to which has been given systematic form, and which has been based upon evidence that admits of being reviewed, estimated and, if possible, submitted to some kind of testing by comparison with other similar experiences. Thus science does not essentially differ from what we call ordinary knowledge; and when we extend the maxim which makes man the measure of all things to the positive sciences, we do not reduce their proof, their claims to acceptance as true pictures of reality, to the testimony solely of immediate sense-perception. No science consists solely or chiefly of data that can be seen, heard, handled, tasted or smelled. But all science, like all knowledge, whether we dignify it with the name of science, or not, is either envisaged or implied in data of concrete and individual experiences. And it is man's reasoning faculties which make explicit what is thus implied. For the method of all science is rationalistic, in the broad meaning of the term. In this work of rationalizing, the imagination, the faiths of reason, and even the emotional attitudes of the human mind toward truth and reality, play an important part. In every individual case, but more emphatically in the case of the race in general, every particular science is a development, an ever growing and never completed achievement of the human mind. And to this development, hypothesis, theory, deduction from known or assumed principles, are all as important and indispensable as is the correct and guarded use of the senses in perception.

In the day when our maxim was first enunciated, there was no positive science

of the physical, chemical or historical sort. There was much acute observation of phenomena, especially in the sphere of the moral, political and social life of man. The ancient Greek maxims for the regulation of the conduct of life have rarely or never been surpassed. The pragmatism of that day was in important respects, both more dignified and more satisfactory than the pragmatism of the present day. The Sophists were pragmatists of the most accomplished rank. But neither ancient nor modern pragmatism can ever give us science, or account for the existence, or the estimate of the values of science, properly so called. As a commentator on this very Dialogue of Plato has said:

The want of the Greek mind in the fourth century before Christ was not another theory of rest or motion, of being or atoms, but rather a philosophy which could free the mind from the power of abstractions and alternatives, and show how far rest and how far motion, how far the universal principle of being, and the multitudinous principle of atoms, entered into the composition of the world; which could distinguish between the true and false analogy, and allow the negative as well as the positive, a place in human thought.

It is only in comparatively recent times, however, that the different sciences of external nature and of man have devoted themselves intelligently and deliberately to the supply of that which was the want of the ancient Greek world of observation and of thought. The Greeks, for example, observed that a vacuum was created by the suction of a piston above the water in a pump. But the dictum, "Nature abhors a vacuum," was regarded as a sufficient explanation of the fact for more than two thousand years, before it was observed in jest by Galileo, that nature did not abhor a vacuum beyond ten meters. But Toricelli was the first really to explain the phenomenon by bringing it under the law of gravitation. Aristotle had observed—

and how many in our scientific age have observed for themselves?—that the sunlight, when passed through a small square hole, gives a round instead of a square image; but he explained the fact simply by saying that sunlight has a circular nature. It was centuries before astronomy established the true explanation in the fact that the sun itself is a circular body.

It was a combination of the principle sounded like a trumpet-call by Newton—"Abandon substantial forms and occult qualities and reduce natural phenomena to natural laws"—with the modification and improvement of the Baconian method of experimental induction which introduced the new era in the positive sciences of external nature. By following these principles man has made of himself a more accurate and faithful measure of all things; of that which is, how it is; and of that which is not, how it is not. But he still needs as much as ever the further study of himself, as an individual and as a race, in order so to supplement, modify, adapt and otherwise improve the principle, that all the various classes of that accepted and certified knowledge which he calls by the name of science, may benefit by this study.

I come, therefore, at once to what is the main purpose of this paper. It was announced in the second of the questions proposed at the beginning. This question concerns the more fundamental of those relations in which the study of man stands to all the other positive sciences. Generalizing these relations, I will say that the study of man as the measure of all things is entitled to set forth and expound (1) the method of science; (2) the limitations of science; (3) the ideals of science. And what it is entitled to do for science in general, it may properly suggest as desirable

and true for each one of the particular sciences.

Intelligently comprehended and faithfully interpreted, the study of man, the measurer, is the only way to find out how his measuring-rod ought to be applied to the different objects which come before him in the different classes of his varied experience. Every positive science, and we might almost say every subdivision of such science, has its special, most satisfactory mode of procedure in the search for truth. That this is of necessity so was known to Aristotle as distinctly as it is known to any modern man of science. Indeed, the principle was never better stated than it was by him in the first book of the "*Nicomachean Ethics*." There the great Greek thinker holds that the matter of a science, *i. e.*, the facts or conceptions with which it deals, must determine its method or form, according as they admit of being stated with more or less "precision" (*Ἀκρίβεια*). But the Greek word which I have imperfectly translated by the English word "precision" means in Aristotle's use of it a combination of mathematical exactness, metaphysical subtlety, minuteness of detail and definiteness of assertion. And as applied to the form of science, or study of one aspect of man, namely, the ethical, which he is proposing to consider, he distinctly states that mathematical exactness is quite unsuited to ethics; that we must not expect too much subtlety, and that too much detail is to be avoided. In this respect his view is more liberal and more true to the nature, limitations and ideals of human science than is that of Sir Isaac Newton when he insists that all "natural phenomena," including the biological, shall be reduced to "mathematical laws." For every step in the evolution of science, as subjected to the conclusions derived from a study of man,

shows that a knowledge of qualities and relations of quality, many of which do not admit of a reduction to mathematical laws, is an indispensable part of all the sciences which deal with natural phenomena.

Every particular science, and, if you please, every form of experiment in each one of them all, should be allowed to determine its own method in the details of its observations, testing the alleged facts, and obvious conclusions from the facts. There is really no reason for assuming a sort of holy mystery about scientific method in general, or about any particular scientific method. Method is any means of arriving at the truth of reality. The greater truths of science, as well as of religion, have always been revealed to gifted—and for my part I am willing to say, inspired—minds, as flashes of intuition, fortunate guesses, hypotheses which as yet awaited verification but shone with that light which announces the clearer vision of the approaching day. I have always had a sneaking sympathy with that schoolboy who, when he came home from school snivelling because he could not do the sums in mental arithmetic set by his teacher, and his mother reminded him that, of course, he had been taught at home the correct answer to them all, replied: "Yes, of course, I know what the answer is, but I can't get the method."

While, then, we admit the right and repose the obligation to any special form of technique, as a matter for the particular sciences to decide for themselves, we still insist that the nature of the human mind and of its development in the individual and in the race is the source of all the experience which determines the successes and the failures in the use of every particular method in each of the particular sciences.

Still more definite but brief statements

with regard to the doctrine of method which the relativity of all knowledge makes imperative would seem in place at this point. If man is to take even his preliminary measurement of things, of that which is, how it is, and of that which is not, how it is not, by sense-perception, he must use trained senses with inexhaustible patience, and with freedom from prejudice and professional pride and ambition. Some years ago the retiring president of the Association of American Naturalists, in his address at the annual banquet, related this recent experience of his own. He had written to a considerable number of the leading biologists in the country, asking that they should give him just the bare facts as they had observed them, and with no admixture of their own views in explanation, upon a certain matter which he was engaged in investigating. "Even so," said this scientific observer, "I could not get the simple unsophisticated facts reported." How many biologists and physiologists in the world at the present time, whatever confidence they may have in the ability and sincerity as an observer of Dr. Bastian, are sure he is giving them just an unprejudiced statement of the facts in proof of his theory of spontaneous generation?

The psychological study of sense-perception, as strengthened by the anthropological study of man's progress in knowledge, shows with undoubted clearness, not only that the details of every man's sense-perceptions are his very own and quite unique, but also that the influence of habit, expectation and interest, contributes largely to what the senses are bound to perceive. But the true doctrine of scientific method which follows from the study of man as a measurer of things by his senses, logically followed, does not land us in an absolute distrust of the senses, in a gulf of scepti-

cism and agnosticism with regard to all human knowledge. The rather should this study serve as a reminder, how uncertain and slow is the laying of solid foundations for the building of the temple of science; but also, how solid those foundations, when well laid, actually are; and how noble the temple which man is erecting toward the skies, on these same foundations.

Among a certain class of psychologists and philosophers—I am ashamed to confess it—there has been much deprecating and even sneering, directed toward the stern control of the logical faculties in the discovery and proof of the nature of reality. “The will to believe,” or the leap of emotion to conclusions affecting the nature of reality, has been attractively offered, and far too freely accepted, as a substitute in science as well as in religion, for the use of reason under the control of reason’s lawful working. But the study of man utters a loud warning against all this. Even a truly scientific mind may express itself and its findings in an alluring rhetorical style. But such a style can never be safely trusted as evidence for, however effective it may prove in exposition of, the truths of either common life or science and philosophy. Logic may be fervid, but it must still remain logic, if it is to be offered in proof of truth. On the one hand, it is true that a purely logical or dialectical construction of scientific theory, after the Platonic or the Hegelian method, when it cuts itself from the bonds which tie it down to concrete facts of more or less nearly universal experience, is not man’s way to measure most faithfully the truth of things. But, on the other hand, it is equally the fact that only by the use of the intellect, the logical or so-called dialectical faculty, can the truth be explicated and interpreted as it lies hidden in the facts. The history of scientific progress shows beyond all ques-

tion, that it is not great collectors of facts, but great thinkers reasoning concerning the meaning of the facts, who have most contributed to this progress.

An additional consideration of no small importance which is made quite clear by the natural history of the individual mind, as well as by the natural history of the race, is this: Knowledge is not only a matter of development, of progressive achievement, in the individual and in the race; it is also a matter of degrees. Any body of knowledge, no matter how strictly it may be entitled to the term science, will necessarily consist of propositions that are made with quite different degrees of assurance. This truth should always be frankly acknowledged in the methodical procedure of every science. Every positive science will, of course, aim to have its different conceptions, so-called laws, and fundamental principles hang well together. It will also attempt to fortify itself by coming into relations of mutual support with the other most nearly allied sciences. It will, above all, test its own conclusions by the amount of agreement which its own best students and trained experts have been able to reach as exponents of the best intellects of the race, in their prolonged and unprejudiced application to the problem of interpreting the experience of the race. But every science will also remember that the very method of science, as inexorably fixed by the nature of man’s intellectual processes, makes it necessary to discriminate different degrees of knowledge, with shifting degrees of certainty and changing claims to importance, as the knowledge of the race advances in clearness and comprehension.

In this connection it is worth while simply to call attention to the fact that the mental attitudes of scepticism, criticism and agnosticism are indispensable and val-

uable factors in all scientific method. Every investigator who attempts to employ the proper method in measuring the things of his special science, is bound to be, always a critic, often a sceptic, oftener still an agnostic. But every investigator is also yet more imperatively bound to be critical, sceptical, agnostic, in right directions; and toward the different conventional opinions, and accepted conceptions and laws constituting the body of that science, in accordance with the varying degrees of evidence and proof.

One thing more on this point. The study of man in any broad and sympathetic way shows us unmistakably that an essential element in all scientific method is a certain indestructible confidence of reason in its own ability, by repeated trials and successive approaches, to reach the truth of things. Man as the measurer of all things is somewhat like those conceited tailors to whom we are sometimes compelled to resort in our efforts to get a perfectly fitting suit of clothes. He is always trying on the coat and altering it, until he has reached the limit of the cloth he has sold us; and then we must be contented with his assurance that it fits us perfectly, while in our secret thought we are troubled with the suspicion that it fits us only fairly well. At any rate, for the present the process of fitting can no further go. At the annual meeting of the British Association in 1904, there were two things, according to the reports in the newspapers, on which those in attendance were all agreed. One of these was that they had never before had quite so fine a time socially; the other was, that in none of the branches of the association was there any one where all the members were in agreement upon any one thing.

Cast a glance over the history of science in general, or over the history of any one

of the particular sciences. Those who scorn philosophy under the pseudonym metaphysics are fond of making merry over the persistent and universal lack of agreement on any one point, of the philosophers from the beginning of reflective thinking until the present time. But the simple fact of history is that the more fundamental tenets of philosophy as held by the different schools have been far less subject to change than have the important conceptions and so-called laws of the particular sciences. What enormous changes have taken place in all these sciences since the improved methods of studying their data have gained general acceptance and been put into general practise! Each one of these sciences is accustomed to boast: In the last half century or less we have made all things new. And with regard to the future of science the words of Scripture are scarcely too strong to describe its apocalyptic vision:

And I saw a new heaven and a new earth; for the first heaven and the first earth are passed away.

All man's voyage on the sea of knowledge, for the discovery, mapping out and exploiting of the new domains of science, is strewn with the wrecks of voyagers in the distant or near past. Never before were so many vagaries and visionary schemes and unproved hypotheses demanding attention and credence. But never before was the fleet of voyagers so numerous, so competent, so sound, so sure of its future, as at the present time. How can such things be? How can the measurer always be making such misfits, spoiling so much cloth, and annoying so much his patient, trustful customers, and yet retain his own immeasurable self-conceit? There are two reasons which establish the sufficient answer to this question. One of these is the indestructible faith of human reason

in itself. It hesitates, it stumbles and makes mistakes and either confesses and corrects or stubbornly adheres to them; but it never despairs or is utterly confounded. The other reason is this: History shows that this confidence is more and more, in fact, justifying itself. All progress in knowledge depends ultimately for its justification on this self-confidence of human reason; but all actual progress in knowledge is a further justification, in fact, of the confidence on which it depends. Man has faith in himself to know; in exercise of this faith, he actually attains higher and higher degrees of knowledge. While, then, constant criticism, frequent scepticism, much rather persistent agnosticism, are attitudes of the human mind toward reality, which should always characterize the method of science; scornful criticism, despairing scepticism, universal agnosticism, are essentially antagonistic to the true spirit and hopeful method of science. And those who cherish such views of the relativity of all knowledge are dissenters from the one form of faith which underlies all particular forms of faith, intellectual, social, religious. An ever present and essential feature of man's rational being is rational faith, or reason's own confidence in itself as the organon of truth.

While, then, each particular science has its own special methods of procedure in the discovery and testing of its own conceptions and laws, there is a certain universal method; or, the rather, there are certain general considerations touching a universal method, which all must observe. Three rules of method, confirmed by the psychological and anthropological study of man, provide for the patient, unprejudiced use of perception, by way of self-consciousness and through the sense, of the facts; the consistent and controlled use of the logical faculties in the interpretation and explanation of these facts; and a justi-

fiable faith in reason as opposed to the positions of a despairing agnosticism. It is not the ancient Sophistical or the modern pragmatic interpretation of the Protagorean maxim, Man is measure of all things; of that which is, how it is; and of that which is not, how it is not, that can guide us into the safe and fruitful method to be pursued by the positive sciences. But, then, it is a comfort to know that even those devotees of these sciences who confess a faith in this interpretation, never take their faith with any large amount of practical seriousness.

A second important way in which the study of man is related to all the sciences concerns the limitations of all science. We are all familiar with the many mistaken predictions as to the limitations of particular sciences which have been made in a merely empirical way. In the "*Memorabilia*" Xenophon makes Socrates remark upon the impiety of men in trying to describe how the gods made the world of things; since all knowledge of this sort is forever beyond the limits of human faculty. In the "*Timæus*," however, Plato makes Socrates indulge in the wildest speculations, in dreams exceeding those of the poet and resembling those of the madhouse, as to how this same world may have been made. No sane student of science now believes that the actual limitations of science are of either sort—either that asserted in the "*Memorabilia*" or that notably transcended in the "*Timæus*." It is the business of science—a matter of obligation rather than a mark of impiety—to know how the natural universe was made and is being made. But when the mind assumes to dream its way into this kind of knowledge, it grossly violates the laws which inexorably fix for all time its impassable limitations. Within the fields of science itself there are constantly occurring

dogmatic statements as to what is intrinsically possible or forever impossible, for the endeavors of human knowledge. Have we not been told that the distances of the fixed stars could never be measured; that the achromatism of lenses could not be carried beyond a certain point, which has already been considerably surpassed; that steamships could never cross the ocean and airships never sail the air, in safety; that synthetic chemistry in the laboratory could never simulate the products of animal and vegetable organisms; that the speed of the nerve current could never be measured, etc., etc.

But what does all this purely empirical way of fixing the limitations of science amount to in the respect of justifying our attempts to regulate the hopeless waste of man's endeavors to know the forever unknowable? Even to-day we may be just as ignorantly—with an ignorance even made more exasperating by the fact that it is so often the outgrowth of our conceit of knowledge—denying the alleged facts of telepathy as was Newton when he refused to explain gravitation as *actio distans*. But whether this or that particular prediction come true or not, this is not the point. The point is this: that by the study of man we are able to fix certain limitations to all science which are inherent in the very nature of man himself and in his relations to that larger nature of which he is a part. It is to the consideration of this sort of limitations that we now devote a moment's attention.

That the senses, from the nature of the psychophysical organism which they serve, are limited in capacity, is a matter of course. Their anatomical structure and their forms of functioning, physiologically considered, require that the range and accuracy of their observation should be confined within certain limits, both of space

and of time. In the eye, the size of the rods and cones; in the ear, the physical construction of the bony and muscular parts of the cochlea; in the skin, the frequency and arrangement of the temperature spots and the pressure spots—all these special limitations of the organism are limits to the measuring power of human sense-perception. Let these physical limitations be changed, either in the direction of improvement or of depreciation, and there would still be similar limitations inherent in the organic structure of the race, and varying with different individual members of the race. In all the various realms of sense-perception, there will always be that which lies beyond, and which can only be conjectured, or at best reasonably inferred, but which can never become immediately perceived by human senses. Surrounding the expanding island of the visible world will be the boundless sea of the invisible; of that which can be touched and handled, the many things that no skin is sensitive enough to feel and that no hand can grasp.

These limitations of the senses set their limitations to the pictorial imagination, or imaging faculty, as distinguished from what logicians have been accustomed to call "pure thought." How things would look, the like of which no eye has ever seen; how things would sound, the like of which no ear has ever heard, will remain questions to which the experience of measuring all things with the senses can give no answer.

But there are other irremovable limitations to human knowledge which are even more important, although more difficult to make obvious. These are limitations inherent in the very constitution of the intellectual powers. The intelligence of man has its own way of working, its laws of behavior, its inescapable modes of operation, to whatever subject it may be applied.

The attempt has indeed been made to account for forms, laws, innate ideas—call them what you will—as the results of a process of evolution. In my judgment, such an attempt must always remain a complete failure. The so-called primitive man in the long gone-by ages reasoned in substantially the same way as that in which the German professor of physics or the American financier or politician reasons to-day. Nor does it appear that the savage peoples of the present time have essentially different minds from our own, or are intrinsically inferior in the acuteness, speed and accuracy with which they reason. Their limitations, as compared with ours, consist chiefly, if not wholly, in the extent of the accumulations of experience with a wider world of things and of men, which lie behind them in history and which constitute their present environment. But we as well as they, and no less truly than they, when we measure things by minding them, know them only according to the formal limitations of our own minds. These limitations concern the comprehensiveness, the certainty, the range, both toward the large and toward the small, the simple and the complicated. The infinite and the infinitesimal may be symbolized and carried as symbols through complex mathematical calculations; but they can never be envisaged by the senses or comprehended by the intellect.

This sort of irremovable limitations surround all the growth and all the achievements of the particular sciences, and might be set forth at any length in the discussion of the categories of science. But such a discussion would be too technical for our present purpose and would take us much too far afield.

Some illustration of what is meant will serve our present purpose. The history of the growth of science for two thousand

years shows many curious attempts to dispense with the obligations put upon the human intellect by the so-called categories, or fundamental and irreducible forms of conceiving of reality, that seem to flow from the very nature of the intellect itself. This effort among the students of physics is particularly insistent and even violent at the present time. But it is just as certainly doomed to failure now as it has ever been. For example, we are treated to a science of physics which would do away with the realistic conceptions of substance and cause, and would substitute for them the more impressionistic and phenomenal conceptions of motion and change. For do we not, with our senses, which are the measure of all things, of that which is, how it is, and of that which is not, how it is not, become actually aware of motions and of changes? But who ever saw, heard, felt, smelled or tasted, of a substance or a cause, in the metaphysical meaning of these words? Go to, then! Let us banish metaphysics and confine our scientific measurements to what the senses can actually perceive. But the conception of motion without this adjunct or underlying conception of something real that actually moves, or the conception of a change that is not caused, or compelled by, or otherwise to be attributed to, some actually existent agent, is a ghostly and intolerable conception. And the world in which relations of motion are supposed to be the sole topic for scientific investigation, is a ghostly and not a real world. But we may always observe by reading between the lines that the "scientist," because he is also a man, and is under the limitations of human intellect, has allowed to sneak in at the back door the very conceptions which he has more or less impolitely dismissed from the front. He must have a "that-which" as substance for his observed motions and as a point of

attachment for his observed changes. For reality is not made up of modern scientific, any more than of ancient philosophical, abstractions. It is, the rather, a theater in which real things are always actually doing something to one another, and in which each one is having something done to itself. There is nothing which the student of physical science more needs to learn from the study of man than that he himself is of necessity a metaphysician, and can only choose between some wisely and well thought-out metaphysical views, and a naïve, crude and misleading metaphysics of his own uninstructed self.

But the final question respecting the limitations of science as they are expounded by the study of man is this: Are they limitations of ignorance or limitations of knowledge? In other words, because there are inherent and inescapable limitations to the human intellect, are we to conclude that man as the measure of all things can really know nothing, just that it is and how it is, or are we to conclude that his knowledge, although never complete and all-comprehensive, is nevertheless knowledge indeed? And by "knowledge indeed" we mean that the real world and its actual happenings are in fact, progressively being more largely and accurately known by the combined achievements of the race? The proof of this faith, if there be proof, belongs to a department of philosophy which we are accustomed to call epistemology or theory of knowledge. In this connection I am only expressing my faith when I say that it is the same as the faith of the race.

Finally, the study of man is entitled to say what the true and worthy ideals of science are. For the scientific mind, the tenets of modern pragmatism with respect to the nature and meaning of truth can never be permanently satisfying. For

science, knowledge has more than a merely practical value, and its tests are something more, and different from the mere success of its practical working. For science, knowledge has an ideal value. We are wont to express this by speaking of the worth of science for science's own sake. But the better, because the truer way to express this ideal is to say that knowledge as knowledge, and science as science, has value for man's sake. And this is because man's mind craves for, feeds upon, finds its satisfaction, uplift and refinement in, the growth of knowledge. To the human mind, or spirit, when it awakens to a realization of its call and its obligation to realize its own higher forms of privilege, and to improve its best opportunity, science affords a satisfaction that has a value of its own.

This is not to say that science has not contributed, and is not bound and glad to contribute, to the so-called practical and utilitarian in the life of man. Chemistry is not pursued with eagerness and satisfaction, and almost religious awe before the mystery of material existence, as a purely mercantile affair. But modern chemistry is transforming almost every branch of modern industry to the great practical benefit of mankind. Modern physics is not cultivated as the servant of the U. S. Steel Corporation, or the General Electric, or the Mercantile Marine monopolies. But the founders and promoters of these corporations owe every dollar of their legitimate earnings or of their graft, and the public owe all the material benefits which have fallen to them from these corporations, chiefly to modern physics.

The satisfaction of man's rational aspiration for knowledge is not, however, the only ideal which the study of man recommends for confidence and intelligent pursuit, to the other sciences. Every science,

no matter how seemingly remote from current human interests, and from man's daily life, may reasonably cherish a spirit of devotion to the social ideal. In educational circles there is just now great debate over the comparative values of the studies called abstract and those called practical, as constituting a preparation for the duties and responsibilities of "real" life. While admitting the reasonableness of this distinction and the value of certain proposals to alter the disposal of time and attention to be allotted by the average man to the two, we wish now to insist upon the thought that no form of science need be pursued, or ought to be pursued, without regard to the relation in which its pursuit stands to the social ideal. The pursuit of knowledge for knowledge's sake is itself a moral benefit to the normal man. And you can never bring about the social ideal, or advance far toward it, without discipline in the pursuit of knowledge. One of the ideals which science prizes and promotes is the ideal of a society, and finally of a race, which is so disciplined in knowledge that it may know how to be wise and upright in conduct. For, although such discipline is not the whole of what contributes to the moral and religious uplift of the race, without such discipline moral and religious progress is impossible for the race.

Hovering over all like a vast but glorious cloud that is being illumined, through the rising mists, by the rising sun, is the ideal to which the combined work of all the sciences is being directed for its better discovery and interpretation, the ideal of a universal order which has at its core, and through all its historical evolution, the unity due to rational mind. This conception in its modern outlines has been won by the toil of thousands of observers and thinkers, and slowly expanded and guaranteed, as it were, by the experience of the

race. It is confessedly incomplete; perhaps it will always remain incomplete. For reality itself is no closed and once-for-all finished affair. But that the world is a realization in time and space of some such ideal as science has built up—an ideal unity of order, beauty and meaning—this is the growing conviction upon which the particular sciences, from their different points of view, and by their different methods, have been converging.

I must ask your further indulgence while I close this paper—already prolonged to an excessive length—in a fashion somewhat sermonesque, *i. e.*, with two practical and hortatory applications.

This view of man as the measure of all things calls upon those who engage in the scientific study of man, whether from the psychological or the anthropological point of view, for comprehensiveness and catholicity. All the other sciences are becoming more definitely tributary to the study of man. His marvellously complex and delicate organism traces its history through indefinite ages of evolution to an unknown and probably undiscoverable past. The description of this organism requires the combined results of the physico-chemical and biological sciences. What we call his mental and social nature and development enlists the efforts of the whole round of the psychological and historical sciences. But we are not ready for a complete and just estimate of the capacity of man as the measurer of all things until we have studied him as a speaking animal, a being with moral, artistic and religious ideals; and with a certain limited though genuine capacity for a self-controlled development in pursuit of these ideals. In a word, both psychology and anthropology are under the obligation to extend their studies, in the interests of comprehensiveness and catholicity, so as the better to understand and

master the spiritual nature and the spiritual development of the individual and of the race.

And, finally, our view of man as the measure of all things is an exhortation to an increase of sympathy and of sympathetic cooperation among all the different sciences. Of the particular sciences and their subordinate branches and subdivisions, there is an ever-increasing number. But their aim is one aim; and in the pursuit of this aim they should be as brethren dwelling together in a spirit of friendly criticism and also of friendly unity. The aim of all human science is the better to understand man by himself, and the greater nature which environs him; and the better to adjust himself to this greater nature, in the pursuit of his economic, social, artistic and religious ideals.

I venture to close with the words which Plato puts into the mouth of Socrates as he closes his conversation with Theætetus:

But if, Theætetus, you have or wish to have any more embryo thoughts, they will be all the better for the present investigation; and if you have none, you will be soberer and humbler and gentler to other men, not fancying that you know what you do not know. These are the limits of my art; I can no further go; nor do I know aught of the things which great and famous men know or have known in this or former ages. The office of a midwife I, like my mother, have received from God; she delivered women, and I deliver men; but they must be young and noble and fair.

GEORGE TRUMBULL LADD

#### PLEISTOCENE GEOLOGY OF NEW YORK STATE. II

##### LAKES

*Glacial Lakes: Occurrence.*—The term "glacial" is used by the writer to include only lakes which existed by virtue of a glacier ice barrier. The lakes and lakelets now existing and called "glacial" by some authors should be discriminated mostly as morainal or drift-barrier lakes.

The conditions necessary for a glacial lake are a valley or depression sloping toward and blocked by the ice front. These conditions were fulfilled in New York on so large a scale, in area and time, that the state, it is confidently believed, held the largest number and the most remarkable succession, with varied outflow, of glacial lakes of any district in the world. The reason for this superiority is found in the peculiar topography of the western part of the state. In the great Ontario-Erie basin we have a broad depression with its lowest passes on the east and west, and with a deeply trenched southern slope where lie the parallel valleys of the Finger lakes.

The only glacial lakes of which clear evidence is preserved are those which lay against the receding front of the latest ice sheet. But it should be clearly understood that every ice sheet which transgressed the state blocked the waters both during its advance and its recession.

We do not know what portions of the Valley-Heads moraine, which now constitutes the divide and forms the south limits of the basin, were left there by Prewisconsin ice sheets, but we may be quite sure that the lakes during the advance of even the last glacier were somewhat different in dimensions and relations from those of the ice recession, which are the subject of our field study. We may also be sure that the earliest ice invasion found the series of parallel valleys with fairly mature and graded forms, and open clear through to their heads, and the larger ones heading in Pennsylvania. Those earliest ice-impounded lakes must have been longer and deeper in the valleys than the lakes of later episodes, when the valleys had become more or less occupied by glacial and lake deposits. The lacustrine conditions of the episodes antedating the Laurentian ice re-

treat are as yet a matter of interesting speculation. One further difference may be noted between the ice-advance and the ice-recession lakes. The primitive lakes of the ice advance were the lowest in altitude and the most northerly in location and with the lowest outlets. As the ice advanced and closed the outlets the waters were lifted to higher levels and pushed southward. The last lakes of the ice advance being in the heads of the valleys were the smallest, the highest, the most detached and most southerly. The lakes of ice-front recession had precisely the opposite history.

*Erosional Work.*—The lake features that are preserved for our study may be discriminated as erosional and constructional. The erosion phenomena are the wave-cut cliffs. The glacial lakes were commonly too ephemeral or too unsteady in their levels to produce conspicuous erosion features. However, the larger and longer-lived lakes, as Newberry, Warren, Dana and specially Iroquois, have left many cliffs.

*Constructional Work.*—Beach Ridges, embankments of sand and gravel, the bars and spits of wave and shore current construction, are the complement of the erosion work but are much more common and are frequently very prominent features. They have long been recognized by the people as the work of mysterious waters at high altitudes. For long stretches the beach ridges have been utilized for "ridge roads," while the level stretches of wave-base along the beaches have afforded graded paths for railroads and canals. The strongest ridges are those of Whittlesey and Warren in the Erie basin, and of Iroquois in the Ontario basin.

*Deltas:* Of the several shore phenomena deltas are the most useful in proving the former presence and determining the altitudes of the extinct lakes. The production and size of the delta deposits are not wholly

conditioned by the size of the receiving water body, but by the volume of the stream detritus relative to the distributing work of the receiving waters. Hence deltas may be built in small lakes, and these hung-up mounds and terraces of gravel on the valley sides serve well to mark the shores of lakes that were too ephemeral or too small to produce either cliffs or bars. Naturally the deltas occur in the courses of land streams, and a vertical succession of bisected delta terraces commonly indicate the falling levels of the lake. Fine examples of these gravel terraces are found on the slopes of the Finger lakes valleys and some of them are conspicuous features, like the terraces by Coy glen, visible from the Cornell University campus.

*Delta Plains:* Genetically related to deltas are the plains of gravel, sand or clay which may be extended in area and indefinite in limits. Such plains usually represent wave-base, perhaps twenty feet or less beneath the water surface. When partially eroded the remnants present extended horizontal lines, excellent examples of which may be seen throughout the Mohawk Valley and about the Irondequoit Valley east of Rochester, clearly visible from the trains on the New York Central Railroad. Some of the larger valleys declining toward Lake Erie exhibit broad terraces at various levels. A fine display may be seen from the Pennsylvania Railroad from East Aurora up to Machias. Evidently such lake plains can occur only north of the divide. Some plains similar in appearance in the valleys south of the divide fall into the categories of outwash plains or of river flood plains.

Scores of examples of detrital plains built in glacial waters by the land drainage might be cited. In the Erie basin the great plain in the Cattaraugus Valley below Gowanda and that built by Silver and

Walnut creeks between Forestville and Silver Creek villages may be mentioned. A very fine illustration is found on the Rochester sheet. The area between the Genesee River and Irondequoit Bay and between Lake Ontario and Iroquois beach ("Ridge Road") is the submerged delta plain of the Genesee River in Lake Iroquois, now much dissected by present-day streams. The flat stretches about Irondequoit Bay bounded by the 400-foot contour are remnants of the silt plain which in Iroquois time filled the whole breadth of the valley.

Sandplains built by the ice-border glacial drainage are also numerous. These include, for example, the plains on the west side of the Genesee Valley opposite Avon; the eroded area north and northwest of Geneva; the mesa-like plains in the Onondaga Valley at South Onondaga and northwest by Cedarvale; and the plain on which stands the business part of Syracuse.

The very extensive and conspicuous sand plains and terraces on both sides of the Champlain and Hudson valleys, including the great delta plain between Schenectady and Albany contributed by the Iromohawk River, were built in sea-level waters that occupied this depression during the time of the ice removal.

Clay Plains: Where the static waters were wide and deep so as to permit full assorting of the detritus, more or less clay was spread over the bottom in the more quiet water. The best example is found in the Iroquois Lake basin. In the St. Lawrence Valley east of Cape Vincent, Alexandria Bay and Ogdensburg are extensive stretches of finely laminated and deep clays, the glacial origin of which is indicated by the abundance of lime concretions. The heavy clay deposits of the Hudson Valley belong in this class, but were deposited in sea-level waters.

*Morainal Lakes.*—This class includes the hundreds of lakes and lakelets (so-called ponds) now in existence that are scattered over the state and most numerous in the Adirondacks. They owe their existence to the blockade of valleys or drainage courses by glacial drift. The term drift-barrier lakes would be the more accurate name. Great numbers of such lakes have already been obliterated, mostly changed into swamps by marl and peat accumulation or by detrital filling; and all these lakes are doomed to similar ultimate extinction either by filling or draining.

The Finger lakes probably owe their origin in part, at least in their upper levels, to drift barriers.

*Cataract Lakes.*—The most singular and interesting lakes in the state lie in the courses of ancient ice-border rivers. These occupy the plunge basins of extinct cataracts. Niagara to-day illustrates the method in production of a basin or bowl by the excavating work of a large cataract. If Niagara River were to be diverted above the fall so as to extinguish the cataract a rock basin holding a lake would be left in the amphitheater beneath what is now the "Horseshoe" falls. South and east of Syracuse the predecessors of Niagara River plunged over cliffs of the Onondaga limestone in their eastward flow and produced several plunge basins with lakes, two of which outrival Niagara.

The Jamesville Lake, four miles south-east of Syracuse, is a circle of emerald-green water about one eighth mile in diameter, and 60 feet deep, lying in a half-circle amphitheater with perpendicular rock walls 160 feet high. Two and one half miles east of Jamesville Lake, across the Butternut Valley, is Blue Lake, resting in a cataract basin and rock amphitheater equaling the Jamesville in dimensions but not so symmetrical. White Lake, one half

mile north of Blue Lake and Round and Green lakes nine miles east of Syracuse, have basins with low and sloping walls because the rocks are the soft Salina shales.

These lakes were formerly regarded as mysterious and with their enclosing amphitheaters were the cause of much speculation. Their nature was first announced by G. K. Gilbert and the first geologic description in recognition of their true character was by Quereau.<sup>10</sup>

These cataract lakes are very remarkable features, and representing as they do an ancient drainage of the Great Lakes area, held at high levels by the glacier front, they have a scientific and educational value not yet appreciated.

*Lakes of Complex Origin.*—This title is intended to include Lake Ontario and the larger Finger lakes, as Cayuga and Seneca, the genesis of which is not entirely clear. The bottoms of these lakes are below sea-level, and we do not know what depth of drift lies yet deeper beneath the water. At Watkins a well boring penetrated 1,200 feet without reaching rock, which shows drift at a depth 600 feet lower than the deepest part of the lake, and 750 feet beneath sea-level.

It seems probable that the valleys of the Finger lakes are blocked on the north, along the drumlin belt, by deep drift fillings, which can be determined only by borings at close intervals. That these valleys were gouged out by ice erosion, even by any number of continental ice sheets, seems to the writer extremely improbable. If they were so deepened, then the basin of Lake Ontario was probably also scooped by ice erosion. But if the Ontario basin is a

depressed river valley, then the valleys of the Finger lakes must be fairly graded to the bottom of Ontario and be of similar origin. If the Ontario and other basins were excavated by river work and weathering, then it must be admitted that there have been great changes in the height and attitude of the land in late geologic time. But such changes are quite certain. It appears probable that the valley-cutting occurred during a time of land elevation, and that the Laurentian and the Finger lakes basins are the complex product of land warping, land depression, and of glacial drift filling. Until the later Tertiary and Pleistocene diastrophic movements of the area including New York have been determined and the drift-buried valleys mapped by borings the deep lake basins may remain the subject of speculation and dispute.

#### GLACIAL LAKE SUCCESSION

The story of the succession of the glacial waters that laved the receding front of the Laurentian glacier is a dramatic episode in the geologic history. Beginning in small pondlings of water in the heads of the valleys along the north side of the morainic divide, the lakes were enlarged as the ice barrier receded, and were captured, drained, blended or otherwise affected by changes in outlets. The romantic story can not be satisfactorily told in words alone, but requires cartographic representation, and a series of maps has been constructed to show the better known and more striking changes in the ice recession and the lake succession.

The control of the glacial waters depended on the altitude of the lowest passes affording immediate outflow along with the relation of these passes to some ultimate escape. The waters of the Laurentian basin outflow to-day by the St. Lawrence

<sup>10</sup> "Topography and History of Jamesville Lake," by E. C. Quereau, *Geol. Soc. Am., Bull.*, Vol. 9, pp. 173-182, 1898. See also illustrated article by Fairchild in the 20th Ann. Rep., N. Y. State Geologist, 1900, pp. 126-129.

(246 feet). With that escape blocked the lowest pass is at Rome (460 for the water surface) to the Mohawk-Hudson, and which for many thousands of years was the point of escape of the waters while the ice body lay over the St. Lawrence Valley. The next higher pass is at Chicago, which was occupied by the glacial outflow for a very long time, but to reach this ultimate escape the Ontario-Erie-Huron waters were compelled to cross Michigan by the valley of Grand River.

The lowest pass leading southward in New York is at Horseheads, the head of the Seneca Valley, leading to the Chemung-Susquehanna with altitude of 900 feet. These three outlets, Horseheads, Grand Valley, Michigan and Rome were the channels of ultimate escape for the waters of western and central New York until the ice was removed from over Covey Gulf, north of the Adirondacks. In immediate control of the waters of central New York, the Seneca-Cayuga depression and the Genesee basin, there were two localities, the salient or highland on the Batavia meridian and the highland in the Syracuse district. The earliest glacial waters in New York were held in the Genesee Valley, and this continued for a long time as a distinct basin with several successive outlets.

When we consider the glacial lakes and drainage in chronologic order we find that the earlier waters were confined in two separate basins, the Genesee and the Seneca-Cayuga. That for a brief time the Horseheads outlet (Lake Newberry) probably occupied the Genesee Valley, and then for a long time the control was alternately west on the Batavia meridian or east in the Syracuse district. Then, when the ice front weakened on the Batavia salient the westward control was across Michigan (Lake Warren level). All the later flow, subsequent to Lake Warren, was eastward

to the Hudson until the northward flow through Covey Gulf and the Champlain Valley to the Hudson.

The most extended series of glacial lakes was in the Genesee Valley. This long valley, the surviving example of the Pre-pleistocene northward drainage, heads in Pennsylvania, at the terminal moraine, with altitude on the cols over 2,200 feet, and extends across the state to near Rochester, where it blends into the Ontario lowland at about 600 feet altitude. The fall of 1,600 feet in a right-line distance of 80 miles gave opportunity for many successively lower outlets and water planes as the ice released passes on the east or west borders of the basin. Probably the glacial lake history of the Genesee Valley is more complicated than is now known, but no less than eighteen distinct outlets with correlating lake levels have been recognized. Then the drainage was directly into the sea (Gilbert Gulf), and finally into Lake Ontario. In this varied outflow the Genesee glacial waters were contributed to several far-separated river systems. Named in order of time these are: (1) Pine creek-Susquehanna; (2) Alleghany-Ohio-Mississippi; (3) Canisteo-Chemung-Susquehanna; (4) Erie basin (Lakes Whittlesey or Warren)-Michigan basin (Lake Chicago)-Mississippi; (5) Seneca Valley (Lake Newberry)-Susquehanna; (6) Mohawk-Hudson; (7) Champlain-Hudson; (8) Ocean-level waters direct; (9) Lake Ontario-St. Lawrence. Some of these systems received the Genesee Valley overflow more than once, or by different immediate outflow, making the twenty stages in the drainage history as now understood. It would seem unlikely that any other valley in the world can approach the Genesee in the complexity of its drainage history.

The series of seventeen maps depict the waning Laurentian ice sheet with the gla-

cial and marine waters that lay against its receding border. The local lakes in the side valleys of the Hudson depression and about the Adirondack highland are not indicated; and the ice border is more or less generalized. The latter is located definitely along the lines of the ice-border drainage.

lowed up the Hudson Valley, finally reaching the Champlain basin and eventually uniting with the oceanic waters of the St. Lawrence Gulf. The Hudson inlet thus became the Hudson-Champlain inlet and finally the Hudson-Champlain strait, connecting New York Bay with the Champlain Sea. When the ice front backed away

## GLACIAL LAKES OF NEW YORK STATE

Drainage Provinces

	17. Iroquois	Ontario				
	18. Second Iroquois.					
	19. Gilbert Gulf (marine)					
	20. Ontario					

The accompanying chart shows the time relationship of the waters in the several basins of the state. The vertical spacing is only suggestive of the succession of the waters and their geographic relations, and has little significance as to the duration of the episodes.

## MARINE WATERS

During the waning of the latest ice sheet the Hudson-Champlain Valley and the St. Lawrence and Ontario basins were beneath the level of the ocean. As the ice front receded northward the sea-level waters fol-

lowed from the Covey Hill promontory the glacial waters of the Ontario basin, the Second Iroquois, fell to and became confluent with the sea-level waters. The highest plane of the sea-level waters in the Ontario basin is relatively weak and has not been fully determined, but an inferior level of long persistence showing heavy bar construction has been mapped and named Gilbert Gulf. This stage, which includes the series of strong bars at Covey Hill post-office, is depicted in map number 16.

On the parallel of New York City it ap-

appears that the land at the time of the ice recession was at, or perhaps somewhat above, sea-level. Northward the land was increasingly below sea-level. The upraised and tilted water plane which indicates the amount of Pleistocene submergence or of Postpleistocene uplift rises steadily from zero or present sea-level in the district of New York City to over 750 feet on the Canadian boundary.

The supposed absence of marine fossils in the Hudson Valley is doubtless due to the freshening of the waters by the copious glacial and land drainage. Until the episode of the Second Iroquois the flood of glacial waters of the St. Lawrence basin was poured into the Hudson inlet at Schenectady. During the Second Iroquois the glacial flood was merely shifted to the north, and during all the long life of the Hudson-Champlain inlet all the fresh waters were forced south. However, marine fossils are abundant in the Champlain Valley and are found at altitudes the planes of which carry over the Fort Edward divide into the Hudson portion of the great valley.

The detrital deposits formed in the marine waters are large in volume and area. Up the Hudson as far as Catskill the terraces of clay and sand are very conspicuous and afford the materials for brick manufacture on an immense scale. North of Catskill, in the widening valley, the summit sandplains lie back from the river, though lower terraces may yet be seen. While much of the deeper deposits and those in the middle of the valley or beneath the present waters are of glacial origin, the heavy visible deposits are chiefly the deltas of tributary land streams, the greatest being that of the Iromohawk at Schenectady-Albany.

From Troy to Glens Falls the borders of the lower valley are buried in a deluge of

sand, sloping down in terraces toward the axis of the valley. Saratoga lies in the midst of a vast area of detrital marine accumulations. The slow lifting of the valley out of the waters gave the latter an excellent chance to produce level stretches and conspicuous terraces, the latter being more prominent as the steeper slopes approach the middle of the valley. The Champlain portion of the great valley also holds vast sandplains, especially on the larger rivers, as the Ausable, Saranac and Big Chazy.

#### EPEIROGENIC MOVEMENT. DIASTROPHISM

The great changes in altitude of the surface of the state, both before and since the glacial occupation, has already been noted. The relation of the land movement to the burden of the ice cap should be briefly discussed. If the earth's crust is sensitive to long-continued pressures, then the thickness and weight of the ice body becomes an important matter.

Again our lack of knowledge of the duration and diastrophic effects of the Prewisconsin ice caps limits our discussion to the effects of the Laurentian ice body.

At its maximum the thickness of the ice cap over the Adirondacks and the Champlain Valley was probably not less than 10,000 feet. This is equal in weight to over 3,000 feet of rock. Southward the ice decreased in thickness and weight to zero in the region of New York Bay. The amount of postglacial uplift increases from zero in the district of New York Bay to over 750 feet on the north boundary of the state. The correspondence between the thickness of the ice cap and the amount of postglacial uplift of the land is very striking and significant. All about the Laurentian basin the tilted shores of the extinct glacial lakes afford us evidence of the differential uplift of the glaciated territory.

The average northward uplift or tilt of the marine plane in the Hudson and Champlain Valley appears to be about two and one fourth feet per mile, but some higher and as yet uncorrelated shore features in the Champlain Valley suggest a deeper submergence there and a larger rate of uplift. It seems quite certain that the increase of the gradient northward that is apparent west of the Adirondacks must also occur on the east of that mountain mass. The differential uplift between the Iroquois plane at Rome (460 feet) and at Covey Gulf, on the Canadian boundary (1,025? feet), is about 565 in a distance of 149 miles in a direction  $33^\circ$  east of north, giving a slant of 3.8 feet per mile. The grade from Richland to East Watertown is toward 6 feet per mile.

In east and west direction there is small deformation. The Iroquois plane at Hamilton, Ont., is given as 363 feet. At Rome it is 460 feet, which makes an eastward uplift of 100 feet in 225 miles, 0.4 foot per mile.

The steadiness or uniformity of the tilted marine plane in the Hudson and southern part of the Champlain valleys is somewhat surprising. It does not seem probable that all land uplifting was deferred until the ice was removed from a stretch of 200 miles and that the rise and tilting was that of a rigid mass. It would seem more likely that as the weight of the ice sheet was slowly removed it was followed by a progressive wave of land uplift. However, the final result of an epeirogenic wave-like uplift might be a fairly uniform plane, simulating that produced by tilting of a rigid surface.

#### POSTGLACIAL EROSION

Land erosion since the ice sheet disappeared is exhibited in wave cutting by the lakes and canyon cutting by diverted streams. In postglacial ravines New York

state excels. We may recall Niagara, the three ravines in the course of the Genesee, the Ausable chasm, Watkins glen. But there are great numbers of glens or steep-walled rock gorges throughout the state which are quite as interesting and instructive as these, even if smaller and unadvertised.

When applied to the effects of erosion in New York the term "postglacial" needs explanation, for much canyon cutting was effected while the ice sheet still lingered on territory of the state. For example, the Portage ravine of the Genesee began cutting while the ice front was not far away on the north. The Mount Morris ravine, the "High Banks," was in the making while the ice covered Rochester. And the upper (south) section of the Rochester canyon was largely cut while Lake Iroquois waters prevented the excavation of the lower part of the gorge. Certainly a large part of the erosional work in central and western New York and the Hudson Valley occurred while the glacier still covered the northern lowlands of the state, including the Champlain Valley.

#### GLACIAL TIME

The first question commonly asked by the non-geologist is, "how long ago?" We have to admit ignorance of any precise measure of geologic time. Geologists have learned to think in millions of years, and they are not greatly concerned with the precise duration of so short a period as the glacial or postglacial episode. However, precise knowledge is desirable and a yardstick of geologic time must be sought. All attempts to use the present rate of canyon cutting or cataract recession as an index of time have failed, and no data yet discovered have much value.

The history of the ice-front recession with its long succession of lakes and well-

developed river channels compels the extension of our estimates of the length of glacial time, and all studies on glacial geology have the same result.

If we take 10,000 years as a moderate estimate of the life of Lake Ontario, then we must add an equal, and perhaps much greater, time for the lifting of the basin out of the marine waters. Then we must allow at least another 10,000 years for the duration of Lake Iroquois; and the 30,000 years carries us back only to the time when the ice sheet was removed from the western part of the state. This appears to be but a minor portion of the time covered by the waning of the glacier, judging from the maps and the known history preceding the initiation of Lake Iroquois.

If we assume 75,000 years as the time in the waning of the ice sheet, then we seem compelled to add an equal time for the invasion of the ice, with some time in addition for the pause at the terminal moraine. Most glacialists will probably agree that 150,000 years for the length of the latest or Wisconsin ice epoch is a fair estimate. And back of this we have the earlier and much longer glacial and interglacial epochs. The estimates of those best qualified to judge of the length of Pleistocene time are from 500,000 to 1,500,000 years.

#### WORK OF THE STATE SURVEY

The Pleistocene phenomena of the state have been the subject of casual observation and publication for over half a century, and a bibliography would be too large to present here. But the glacial and Pleistocene is the youngest member of the geologic branches of study, and only in recent years has the New York State Museum financed the glacial study as a distinct line of field-work and publication. This assistance, however, has been generous and effective, as the numerous papers and handsome

maps published since 1900, and especially since 1905, will bear witness. The only elaborate and expensive maps and text published under other auspices than the State Museum is the U. S. Geological Survey Folio 169, already cited above. A description of the Moravia quadrangle by Carney was published in 1909 by Denison University, with a sketch map in black and white.

The more important Pleistocene publications of the State Museum are Bulletins 48, 83, 84 by Woodworth; 154 by Stoller, and 106, 111, 127, 145 (in part) and 160 by Fairchild. Earlier papers by the writer are contained in the 20th Annual Report of the State Geologist, 1902, 21st Report, 1903, and the 22d Report, 1904. Previous papers by the writer on the Pleistocene features of the state were published in the *Bulletin* of this society, beginning in 1895, and in other scientific journals.

For effective future work it is desirable that some scheme or far-sighted plan should bring all the glacial studies of the state into harmonious cooperation for the large result. And also that a cartographic scheme should be adopted that will secure maps as uniform in convention and color as possible.

Two important subjects requiring systematic study are the moraines and the drift-buried valleys. The state should undertake the mapping of the buried valleys. It should employ a well-boring outfit to secure data for accurate profiles of the hard-rock surfaces beneath the drift north of the Finger lakes, and wherever the Preglacial valleys of scientific interest are obscured. This would be a unique and popular work for the State Museum. The expense of such exploration would not be large, while the scientific and educational value would be great.

Another duty of the state is the preservation intact of the Jamesville and Blue lakes

cataract features. These splendid evidences of an ancient glacial drainage, antedating Niagara and corresponding in function, should be made state property and preserved for the people. They are scenic features of as much beauty and of much more educational value than Watkins Glen and some other state parks.

HERMAN L. FAIRCHILD

UNIVERSITY OF ROCHESTER

#### THE DIVISION OF EDUCATIONAL INQUIRY UNDER THE CARNEGIE FOUNDATION

MR. ANDREW CARNEGIE has given \$1,250,000 to the Carnegie Foundation for the Advancement of Teaching. The gift was announced on the eleventh, at a meeting of the executive committee at its offices, 576 Fifth Avenue. The gift is in the form of 4 per cent. bonds and the income is to be set aside for special investigation relative to the purposes of the original foundation of pensioning college professors.

The announcement of the executive committee states that the money is to be devoted to the endowment of a Division of Educational Enquiry and makes permanent provision for studies hitherto conducted by the foundation out of its general fund. It is the plan of the trustees to proceed with the new endowment to make other studies similar to those already published concerning medical education and in particular to study legal education in its relation to the supply of lawyers and the cost of legal process.

Mr. Carnegie's letter to the trustees is as follows:

CARNEGIE CORPORATION OF NEW YORK,  
January 31, 1913.

TO THE TRUSTEES OF THE CARNEGIE FOUNDATION  
FOR THE ADVANCEMENT OF TEACHING.

Gentlemen:—Appreciating the valuable results of the educational studies of the Foundation and being of opinion that it is desirable that a fund be established to secure such results and conduct such investigations as may aid you in your work and realizing that sufficient income may not now be available for that purpose, I hereby offer to the foundation the sum of one million and a quarter

dollars four (4) per cent. bonds, to be held and used by the foundation upon the following terms:

I. There shall be organized in the foundation an agency for the study of education and educational institutions, to be designated the Division of Educational Enquiry.

II. Any endowment or funds conveyed to the foundation for the use of such division shall constitute and be held as a special fund and the income alone be used and shall be accounted for separately from the general funds of the foundation and shall be devoted to the purposes hereinafter named.

III. It shall be the function of the Division of Educational Enquiry to conduct studies and to make investigations concerning universities, colleges, professional schools, and systems of education generally, to investigate problems of education affecting the improvement of educational methods, the advancement of teaching, or betterment of educational standards, and in general to investigate and to report upon those educational agencies which undertake to deal with the intellectual, social and moral progress of mankind and to publish such results as the trustees may consider of value.

IV. The income of the Division of Educational Enquiry shall be used in the expenses incident to the performance of the work of the Division of Educational Enquiry as hereinbefore set forth, as may from time to time be undertaken and published by the foundation, but no part of the income of the fund or funds specifically given for the use of this division shall be used in the payment of pensions.

It is my purpose to aid the trustees of the foundation to conduct their work upon broad lines and to enable them to obtain such information as will make the whole endowment of the Foundation of the greatest possible service to mankind.

Yours truly,  
(Signed) ANDREW CARNEGIE,  
President.

#### THE MILWAUKEE MEETING OF THE AMERICAN CHEMICAL SOCIETY

THE forty-seventh annual meeting of the American Chemical Society will be held in Milwaukee, Wisconsin, March 25 to 28, inclusive. A meeting of the council will be held on March 24, at the Hotel Pfister, which is the hotel headquarters. The meetings will be held at Marquette University, Grand Ave. and 11th

St., where every facility is offered for the meetings of the divisions in the center of Milwaukee's business section.

Mr. C. H. Hall is chairman of the local committee and Mr. P. J. Weber, secretary. The finance committee is under the chairmanship of Mr. G. N. Prentiss. Reception, registration and information committees are under the chairmanship of Mr. E. V. Manuel. The committee on arrangement has Mr. H. W. Rohde as its chairman, Mr. F. E. Layman is chairman of the entertainment committee, and Mr. C. R. McKee is chairman of the committee on entertainment of ladies.

The entertainment committee is planning an interesting program, which will be an undoubted success, and special attention is being paid to preparations for the entertainment of ladies at such times as they can not participate in the regular program. Many manufacturing plants will be visited, and although no definite arrangements can be announced in the present circular, it may be stated that Milwaukee contains important works covering the tanning industry, manufacture of iron and steel, by-product coke and gas, manufacture of glue, manufacture of automobiles and automobile parts, automobile tires, packing industry, manufacture of refrigerating machinery, gasoline engines, kerosene engines, and shops of railroad companies, most of which will be open to the members.

All the divisions will meet. It is probable that the Biological Division will be duly organized at this meeting. Members are especially asked to note the excursion to Madison, Wisconsin, on Friday, March 28. The Society has a special invitation from President Van Hise, of the University of Wisconsin, and it is hoped that all those who attend the meeting will also go to Madison. The city is but seventy miles from Milwaukee and is of special interest, being the seat of the state capitol, the University of Wisconsin, the United States Forest Products Laboratory, and the location of a large beet-sugar refining plant, which, if present information is correct, will be in operation at the time of the convention.

All papers for the meeting must be in the

secretary's hands on or before March 7 or in the hands of secretaries of divisions by March 5, in order to be on the program. By vote of the council no papers can be presented at the meeting that are not printed on the final program.

The following are the addresses of the divisional and sectional secretaries:

Industrial Division—M. C. Whitaker (*pro tem.*), Columbia University, New York City.

Physical and Inorganic—R. C. Wells, U. S. Geological Survey, Washington, D. C.

Fertilizer—J. E. Breckenridge, Carteret, N. J.  
Agricultural and Food—G. F. Mason, care of Heinz Company, Pittsburgh, Pa.

Organic—Wm. J. Hale, University of Michigan, Ann Arbor, Mich.

Pharmaceutical—Frank R. Eldred, 3325 Kenwood Ave., Indianapolis, Ind.

Rubber—Dorris Whipple, care of The Safety Insulated Wire and Cable Company, Bayonne, N. J.

Biological—I. K. Phelps, Bureau of Mines, 40th and Butler Sts., Pittsburgh, Pa.

Chemical Education—J. F. Norris, Simmons College, Boston, Mass.

#### SCIENTIFIC NOTES AND NEWS

SIR DAVID GILL has been elected the first honorary member of the Astronomical and Astrophysical Society of America.

SIR WILLIAM TILDEN, F.R.S., the British chemist, has been elected a corresponding member of the Imperial Academy of Sciences, St. Petersburg.

THE gold medal of the Royal Astronomical Society has been awarded to M. Henri Alexandre Deslandres for his investigations of solar phenomena and other spectroscopic work.

THE Langley medals of the Smithsonian Institution are to be conferred on M. Gustav Eiffel, the French engineer, and Mr. Glenn H. Curtiss, known for his development of the hydro-aeroplane.

MR. F. W. HODGE, of the Bureau of American Ethnology, Smithsonian Institution, has been elected a corresponding member of the Société des Américanistes de Paris.

PROFESSOR POULTON, F.R.S., Professor Bourne, F.R.S., and Mr. E. S. Goodrich,

F.R.S., have been appointed to represent Oxford University at the International Congress of Zoology, to be held this year at Monaco.

PROFESSOR A. KEITH has been elected president of the Royal Anthropological Institute of Great Britain and Ireland.

DR. E. B. ROSA, of the Bureau of Standards, gave the address of the retiring president before the Philosophical Society of Washington on February 15. His subject was "The Function of Research and the Regulation of National Monopolies."

PROFESSOR CHARLES LAPWORTH has expressed the desire to vacate the chair of geology in Birmingham University at the end of the current session.

*The Chemist and Druggist*, London, reports the appointment, by the Pharmaceutical Chemistry Section of the Eighth International Congress of Applied Chemistry, of an international commission to continue the inquiry on "Variation in the activity of certain toxic drugs" and to report at St. Petersburg in 1915. The commission named is as follows: Austria, Professor Wilhelm Mitlacher; France, Professor E. Bourquelot; Germany, Professor H. Thoms; Great Britain, Francis Ransom, F.C.S.; Netherlands, Professor L. van Itallie; Switzerland, Professor A. Tscheich; United States, Dr. Rodney H. True. Three secretaries for the commission were also appointed: European Continent, George P. Forrester, F.C.S.; Great Britain, Peter MacEnau, F.C.S.; United States, Otto Raubenheimer.

PROFESSOR H. LOUIS JACKSON, B.S. (Mass. Inst., '05), who has held the position as assistant professor of chemistry in charge of foods at the University of Kansas since 1907, has accepted the position of state chemist of Idaho. He will go at once to Boise, where the laboratory is located.

FRANZ SCHNEIDER, JR., '09, instructor at the Massachusetts Institute of Technology, has accepted the position of sanitary expert to the department of surveys and exhibits, Russel Sage Foundation. For the lecture work that has been carried on by Mr. Schneider, W. C.

Purdy, professor of biology at Geneva College, has been called and will be named assistant in biology.

THE Peruvian government has officially designated Mr. Charles H. T. Townsend director of entomological stations in addition to his title of government entomologist, extending his contract to December 31, 1913. A central station of agricultural entomology is already established in temporary quarters at Lima, for the general investigation of insect plagues of agriculture in the central coast region. It is intended to maintain the branch station of agricultural entomology in the department of Piura, for continuing the investigation of cotton insects and their enemies. A station of medical entomology has been established at Chosica, where an investigation of the blood-sucking arthropods of the verruga zones has already been started to determine what species may be the carrier of verruga fever. Mr. E. W. Rust has been transferred from Piura to Lima, and Mr. J. G. Cateriano has been added to the force. Several graduates from the School of Agriculture will be trained in agricultural entomology, and a graduate or two from the School of Medicine will be trained in medical entomology at Chosica.

THE Museum of Zoology, University of Michigan, will send a second expedition to Whitefish Point, Chippewa County, Michigan, in the summer of 1913, to continue the work started in that region in 1912. The 1913 work, like that of 1912, will be supported by Hon. George Shiras, and the results will be published under the same general title "Results of the Shiras Expeditions to the Whitefish Point Region, Michigan."

PROFESSOR C. E. MCCLUNG, of the University of Pennsylvania, lectured before the Society of the Sigma Xi of that university on February 7, his subject being "Sex Determination."

THE first lecture of the year before the Ohio State University Chapter of Sigma Xi Society was given by Dr. A. W. Gilbert, Cornell University, on the topic "The Method and Scope of Genetics." The officers of the Ohio State

University Chapter of the Sigma Xi Society this year are Dean David S. White of the College of Veterinary Medicine, president; J. S. Hine, associate professor of biology, vice-president; F. C. Blake, professor of physics, treasurer, and James R. Withrow, professor of industrial chemistry, secretary.

PROFESSOR A. M. TOZZER, of Harvard University, during the mid-year period, gave lectures before the various societies of the Archeological Institute of America in the following places: St. John, Halifax, Quebec, Montreal, Ottawa, Toronto, Hamilton, Buffalo, Rochester, Auburn and Syracuse.

ON February 7, Professor Edward L. Thorndike, of Teachers College, Columbia University, delivered in the afternoon a lecture on "Social Instincts" before the department of psychology of the John Hopkins University; and, in the evening he addressed the Educational Society of Baltimore on "Retardation and Elimination in High School."

PROFESSOR J. S. PRAY, chairman of the department of landscape gardening of Harvard University, gave recently two lectures at the University of Illinois on the subjects "Functional City Planning" and "Gardens Old and New."

MONSIEUR J. M. F. DE PULLIGNY, ingénieur en chef des ponts et chaussées, et directeur, Mission Française d'Ingenieurs aux Etats-Unis, New York City, on February 11, delivered an illustrated lecture on "The Public Service of Roads in France," before the graduate students in highway engineering at Columbia University.

ON February 4 Professor G. H. Parker lectured before the Vassar Brothers' Institute, Poughkeepsie, N. Y., on "The Evolution of the Nervous System."

THE Alumni Association of the Michigan College of Mines has published its January number of *The M. C. M. Alumnus*, which is a memorial to Professor George A. Koenig, head of the department of chemistry, who died in Philadelphia on January 14. The number contains a full-page engraving from a late

photograph, a biography and the addresses of the memorial service.

PROFESSOR JULIUS FRANZ, director of the astronomical observatory at Breslau, has died at the age of sixty-five years.

DR. G. DE LAVAL, the well-known Swedish engineer and inventor, has died at the age of sixty-seven years.

THE Civil Service Commission invites attention to the regular spring examinations for scientific assistant, Department of Agriculture, to be held April 9 and 10. The entrance salaries are from \$1,000 to \$1,800. Examinations will be given in the following subjects: agronomy, dairying, entomology, farm economics, farm equipment, forage crops, general farm management, horticulture, library science, nutrition and calorimetry, plant breeding, plant pathology, pomology, seed testing, soil bacteriology, soil chemistry, soil surveying. An examination will be held on March 10 for senior highway engineer, to fill vacancies as they may occur in this position in the office of public roads, Department of Agriculture, at salaries ranging from \$2,000 to \$2,400 a year.

---

#### UNIVERSITY AND EDUCATIONAL NEWS

THE sum of \$75,000 has been subscribed and given to Vassar College to endow a chair of physical science.

IN a recent issue of SCIENCE, mention was made of the bequests of Levi N. Stewart, of Minneapolis, to Dartmouth, Bowdoin and Bates Colleges. In addition Mr. Stewart bequeathed \$75,000 to Colby College.

MR. DAN R. HANNA, proprietor of the Cleveland *Leader and News*, has offered to the Western Reserve University ten thousand dollars a year for establishing a School of Journalism. The school will be coordinated with the other professional schools of the university, and will be its ninth department. Adelbert College, the college of arts and sciences for men, is the oldest department. It was founded as Western

Reserve College in 1826, and refounded as Adelbert College of Western Reserve University in 1882. The School of Medicine was founded in 1843, the School of Pharmacy in 1882 and the College for Women in 1888. In 1892, the School of Law, the Graduate School and the Dental School were founded. The Library School was founded in 1904.

THE actual number of law schools in the United States only increased from 102 to 118 in the decade from 1902 to 1912, according to figures compiled at the U. S. Bureau of Education, but the number of students studying law in these schools increased from 13,912 to 20,760 in same period. There were 3,524 graduates of law schools in 1902 and 4,394 last year. Law students, having a collegiate degree, doubled in the ten years. Financially the law schools show a remarkable advance. The endowment funds increased from half a million to nearly two million dollars; the grounds and buildings tripled in value; and the total income in 1912 was \$1,368,000, as against \$523,000 in 1902. The 387,000 volumes in the law-school libraries of 1902 had grown to 936,000 in 1912.

DR. FREDERIC LYMAN WELLS, assistant in pathological psychology at the McLean Hospital, is conducting a course of lectures and discussions on "Pathological Psychology" at Harvard University.

DR. FREDERICK G. DONNAN, F.R.S., has been appointed to the chair of general chemistry at University College, London, recently vacated by Sir William Ramsay, F.R.S.

DR. WILLIAM J. DAKIN, F.R.S., at present assistant professor at London University, has been appointed professor of biology at the University of Western Australia, Perth. Dr. Alexander D. Ross, of Scotland, has been appointed professor of mathematics and physics in the same institution.

#### DISCUSSION AND CORRESPONDENCE

##### A PLAN FOR THE ENCOURAGEMENT OF MEDICAL RESEARCH

JUDGING by the number of bequests and endowments directed toward that end, the

furthering of medical research is an attractive field for philanthropic endeavor if not for public investment. As one of the rank and file who are working toward the advancement of medical science I would suggest that no method of encouraging such research has heretofore been wholly successful. The foundation of institutes for this purpose is effective in case of the favored few who happen to be reached, but for most scientists (including the clinical variety), who are engaged in teaching in medical schools, who constitute the great proportion of the working force, such foundations are of little assistance.

The most effective plan would seem to be that by which actual accomplishment is rewarded without unduly favoring any one. Such a result could be achieved by the simple expedient of endowing the periodicals devoted to the publication of research so that contributed articles could be paid for according to their merit. Such an arrangement would obviate the most discouraging feature of working in many institutions, the feeling that unusual effort is, from a selfish point of view, not merely futile but even detrimental, in that leisure for reading, recreation and family life is sacrificed without compensating gain.

The plan in operation would be simplicity itself. Rewards would go automatically to those who earned them. The chief difficulty seemingly would be to secure editorial boards fair minded enough to decide justly upon the merits of each contribution, but that difficulty would be by no means insurmountable. In any case to assign a value to a given piece of research would be much easier than to forecast which of a dozen men would be accomplishing the most effective work ten years later, a forecast which, as a matter of fact, has to be made in each instance, before a desirable research or teaching position can justly be assigned.

It is recognized that the best endeavor can not be bought, and that the best rewards of a scientific career are not pecuniary—"but that is another story!" Whatever merit there is in financial encouragement would seem best

to be secured by some such as the foregoing plan.

R. G. HOSKINS

STARLING OHIO MEDICAL COLLEGE

#### GRANA DE BRASILE

TO THE EDITOR OF SCIENCE: I should be glad to learn what grain and what region were meant by "grana de Brasile" in the 1193 commercial treaty between the "Bononienses" and "Ferrarienses" copied by Muratori into Vol. 2 of his "Antiquitates Italicae," p. 844. He mentions (p. 488) the repetition of the same item in a "charta" of 1198.

Capmany's Spanish work on the early shipping arts, etc., of Barcelona copies in Vol. 2 several thirteenth century Catalan tariff lists, three of which (the earliest 1221) for that and other parts, respectively mention, among miscellaneous commodities, "Carrega de Brasil," "faix de bresil" and "cargua de brazil." The usual impost seems to have been two solidos. One of these lists mentions "grana" unqualified. There seems nothing to indicate what material was or was not meant, except the slight negative value of that reference.

It is interesting to see the variations of orthography in these lists, duplicating those of the Brazil west of southern Ireland on the fourteenth and fifteenth century maps, though Fra Mauro adds berzil and the more southern apparently imitative Brazils (Terciera and others) exhibit further vagaries of spelling. The first appearance of Brazil in geography seems to be, so far as reported, south of west of Limerick on the 1325 map of Dalorto.

Was it thence that the "grain" of 1193 and 1198 was supposed to have come? It can hardly be an error for dyes or dye woods, though both grain and dye wood may have been associated with the idea and name of Brazil, as we still write both India-ink and India-rubber.

W. H. BABCOCK

#### CONCERNING GOVERNMENT APPLICATION BLANKS

TO THE EDITOR OF SCIENCE: In former times when one wished to institute a comparison between the various classes of liars, he was accustomed to say "he lies like a horse-thief," or "he lies like a tombstone." Now, however,

those of us who are connected with the teaching profession are given to saying "he lies like a testimonial."

It seems a little too bad that one's natural tendency towards mendacity should be accelerated by no less a person than Uncle Sam. Some time ago I was asked to fill out a blank for an applicant for a teaching position in the Philippine Islands, and among other questions asked me were the following:

8. Is the applicant now, or has he ever been, addicted to the use of intoxicating beverages, morphine or opium?

14. Can you state positively that the applicant's character is unimpeachable, and his reputation for sobriety and morality unquestionably good?

The printed directions state that all questions must be answered and that to say "I don't know" is unsatisfactory. Now I feel confident that the young lady who did me the honor to ask me for a testimonial has not been addicted to the use of intoxicating beverages, morphine, or opium; but I could not make this statement as a positive fact about her or any other acquaintance of mine. Again, I believe the applicant's character to be unimpeachable, but I can not state positively that such is the case. This is a world of surprises and disappointments. I am most optimistic, but not sufficiently so to answer these questions in the affirmative. May we not hope that our new president-elect will take measures to relieve the tender consciences of college professors from the great strain that these government blanks put upon them?

JAMES S. STEVENS

UNIVERSITY OF MAINE

#### SCIENTIFIC BOOKS

*Richtlinien des Entwicklungs- und Vererbungsproblems.* By ALFRED GREIL, Professor of Anatomy, Innsbruck. Jena, Gustav Fischer. 1912. 2 parts.

The crude evolutionism of Bonnet gave place to the epigenesis of C. F. Woeff, and this, too indefinite to give sufficient explanation of the phenomena of cell differentiation, adaptation and inheritance, in turn was supplanted by a newer preformationism, at first

also rather crude, but later becoming more and more refined, until finally it has become almost if not quite metaphysical. To Professor Greil, however, preformationism in any of its forms is a stone of stumbling and a rock of offense, and in the two volumes now before us he attempts to recall the feet of the faithful to the paths of epigenesis, by what he terms, with insistence, a formal or descriptive analysis of the phenomena of development.

He starts, however, with a basic proposition, "the true and fundamental principle of rational comparative embryology," which he expresses in the words of Haeckel, "Aus Gleichartigem Ungleichartiges." He is thus an epigenesist of the epigenesists and his method of analysis is to proceed from this assumed truth to reconstruction of the embryological history. The first part of the treatise is practically a reprint of a paper recently published in the *Zoologische Jahrbücher*<sup>1</sup> and is a description of the phenomena of development as seen by a thorough-going epigenesist, who is also a firm believer in the biogenetic law. In the second part special problems, such as adaptation and variability, inheritance and sex-determination, are similarly surveyed and in a somewhat extended appendix the various theories of Roux, R. Hertwig, Rabl, Mehnert, Kassawitz, Fick and Godlewski are reviewed and criticized, with the same richness of dialectic that pervades the entire work.

For the author wields the pen of a ready writer, which unfortunately frequently leads him into unnecessary repetitions and verbosity, which extend over seven hundred pages what might have been clearly and forcibly presented in perhaps half the space, to the greater comfort and satisfaction of the reader. But even with due allowance for redundancies, the ground covered is so extensive as to preclude the possibility of a review or even a bare enumeration of the various questions discussed, and it must suffice to repeat that the main thesis of the work is the all-sufficiency

<sup>1</sup>A. Greil, "Ueber allgemeine Richtlinien des Entwicklungs- und Vererbungsprobleme," *Zool. Jahrb.*, Bd. XXXI., Abt. für allgem. Zool. und Physiol. der Tiere, 1912.

of epigenesis. That is the one and only power, and formal analysis is its prophet. Professor Greil presents a strong case, but it must be confessed that he does not and, indeed, in the present state of our knowledge, he can not yet remove the difficulty that has forced so many thinking zoologists into preformationism, namely, an explanation of how differentiation is possible by epigenesis. One may glibly talk of cellular interaction, of effects produced by quantity and quality of the food and by the outside environment, and of the determination resulting for the chemical constitution of the ovum, but until we have concrete evidence of how these or other factors act in the production of differentiation epigenesis will continue to be no explanation. And, after all, if the last named of the above factors be admitted, is it not merely carrying preformationism back to its ultimate limits and making it identical with epigenesis?

J. P. McM.

*Origin and Antiquity of Man.* By G. FREDERICK WRIGHT, D.D., LL.D., F.G.S.A. Oberlin, Ohio, Bibliotheca Sacra Company. 1912. Pp. xx + 547. Illustrated.

As an introduction Professor Wright discusses the origin and antiquity of the earth. He inclines toward a very moderate estimate of the length of geologic time and hence of the human period, which began when man became a tool-user. To him the ancient civilizations of Babylonia, Egypt, Crete and Central Asia were of a high order. These rare blossoms in the springtime of history were each nurtured by exceptional geniuses instead of being the product of a gradual unfolding.

The diversity of languages is invoked as an aid in the measurement of man's antiquity. In view of the rapidity with which children when isolated invent a language of their own, the author believes the evidence of an extremely great antiquity of the human race drawn from the diversity of language at the dawn of history to be far from conclusive.

In the chapter on the "Origin of the Races of Europe" (p. 105), the author states that

the stone implements of the Scandinavian shell heaps "have usually been polished and sharpened by rubbing; this justifying their assignment to the 'smooth stone age.'" The fact is, artifacts of polished stone characterize a later stage and not the early shell-heap phase of the neolithic. Neither do the "chipped flint daggers of exquisite form" and the perforated diorite axes (pp. 125-126) come from the "kitchen middens," but from the stone cist burials of a later epoch. The statements that the Cro-Magnon race is of neolithic age (p. 115) and that it did not appear until after the mammoth had become extinct (p. 116) would not be admitted by the best authorities. Cro-Magnon is paleolithic and the mammoth lived on until the close of the Magdalenian, as attested by the mural art of the caverns, especially at Font-de-Gaume; and hence was a contemporary of the Cro-Magnon race. In the same paragraph by inference one is led to suppose that the engraved figure of a reindeer from Thayngen is the work of a neolithic craftsman; when on the contrary it is paleolithic.

As might be expected of Professor Wright, much space is devoted to man and the Glacial period, not only in the old world, but also in the new. His estimates of the length of time that has elapsed since the beginning of the Glacial period are moderate. He believes that the Glacial period was practically a unit, there being four phases instead of four distinct epochs, thus differing from some of the most noted living glacialists. The cause of the Glacial period is assigned to land elevation and its disappearance to a subsidence, factors which probably played a rôle in the great climatic drama, but which might have been correlated with other factors such as the changing condition of the sun itself and in the atmosphere.

But little space is given to cultural and somatic evolution, in which field many important results have recently been achieved. The Magdalenian polychrome frescoes on the cavern ceiling at Altamira are referred to as of Aurignacian age, an error into which Sollas ("Ancient Hunters") also fell.

The author's point of view might possibly be best reflected in a few quotations: "Our earliest knowledge of man is of a being fully formed and in possession of all the faculties of his kind" (p. 389). "On the important question of man's first arrival on this planet we may for the present possess our minds in peace, not a trace of unquestionable evidence of his existence having been found in strata admittedly older than the Pleistocene" (pp. 341-2). "The simple arithmetical calculations made above show that when once started, the dispersion over the world, the diversification of the races, the differentiation of languages, and the development of ancient civilization may easily have come about in the course of four or five thousand years, if not in half that time, and that the extension of prehistoric time for eight thousand years affords superabundant opportunity for the growth and development of all the peculiarities and institutions of man as first made known to us at the dawn of history" (p. 493). "The antiquity of man therefore so far as the question depends upon his connection with the Glacial epoch, is not proved to be, even when we allow a generous margin, greater than twelve or fifteen thousand years" (p. 494).

The chapter preceding the "Summary and Conclusion" treats of "The Biblical Scheme." The work has the welcome merit of an engaging style, possessing to a degree the charm of the author's personality. Another attractive feature is the "Appendix" of copious notes and references.

GEORGE GRANT MACCURDY

YALE UNIVERSITY

#### SPECIAL ARTICLES

NEW AND EXTINCT BIRDS AND OTHER SPECIES  
FROM THE PLEISTOCENE OF OREGON

MANY years ago I published in the *Journal* of the Academy of Sciences of Philadelphia an account of the fauna of the Oregon desert region during Pleistocene time. This account was based upon a large collection of fossils sent me for the purpose by the late Professor E. D. Cope, who, with his assistants and a

few other naturalists, had brought this valuable material together. By far the greater part of this consisted of the fossil bones of birds, the mammals and fish having been described by Professor Cope in *The American Naturalist* and elsewhere.

The results of my share of the work have long since passed into the literature of the subject; and, as these are fully set forth in my academy memoir, they need not be especially reviewed in this place. It may only be noted that I announced, for the first time, the discovery of a long list of birds, based on the fossils referred to, the majority of which coincided with species and genera of existing forms, while a somewhat formidable array were extinct and new to science.

At the time my examination was made, the skeletons of existing birds at my command were entirely inadequate for the purposes of making reliable diagnoses and references. During the past twenty years, however, such material has been vastly increased in our museums, especially in the U. S. National Museum, and for the use of this in the present connection I am much indebted.

Several years ago, what may be collectively designated as the Cope collection from the aforesaid region was purchased by the American Museum of Natural History in New York City for its paleontological department; and only a few months ago Dr. W. D. Matthew, the curator of that department, shipped me to Washington the entire collection for the purpose of a complete revision. This task is now practically completed, and the object of the present article is simply to publish an advance abstract as an announcement of the additional birds of the region in question, the fossil remains of which I have found to exist in the aforesaid collection, and a small collection from the same localities (Silver and Fossil lakes), which belongs to the U. S. National Museum. The new species will be fully described in the forthcoming contribution on the subject, accompanying which will be found upwards of 600 figures illustrating the entire avifauna of the Pleistocene of Oregon, in so far as their fossil remains are concerned.

The list is as follows, each species in it, with one exception, being announced for the first time:

1. *Colymbus parvus* (extinct).
2. *Podilymbus magnus* (extinct).
3. *Centrocercus urophasianus*.
4. *Mergus americanus*?
5. *Mergus serrator*.
6. *Mergus* sp.?
7. *Marila americana*?
8. *Marila valisineria*.
9. *Marila marila*.
10. *Marila affinis*?
11. *Marila collaris*?
12. *Charitonetta albeola*.
13. *Histrionicus histrionicus*.
14. *Polysticta stelleri*.
15. *Erismatura jamaicensis*.
16. *Branta c. hutchinsii*?
17. *Branta c. minima*?
18. *Branta bernicla*.
19. *Olor columbianus*.
20. *Olor buccinator*.
21. *Olor matthewi* (extinct).
22. *Ardea herodias*.
23. *Botaurus lentiginosus*.
24. *Aquila chrysaetos*.
25. *Haliaeetus leucocephalus*.

*Erismatura jamaicensis* has been previously announced by Mr. L. H. Miller in the *Bulletin* of the Academy of Natural Sciences of California. The three new extinct birds found, and the descriptions of them, will appear when the memoir is published.

R. W. SHUFELDT

November 18, 1912

#### PROCEEDINGS OF THE ENTOMOLOGICAL SOCIETY OF AMERICA

THE seventh annual meeting of the Entomological Society of America was held at Cleveland, Ohio, December 31 and January 1, in the auditorium of the Normal School. The meetings were all well attended and enthusiastic. The following papers were presented:

C. BETTEN, Lake Forest University: *An Interesting Feature in the Venation of Helicopsyche, the Molannidae and the Leptoceridae*.

In the trichopterous genus *Helicopsyche* radius of the fore wing is found in primitive condition, i. e.,  $R_1$  is simple and the sector is dichotomously branched. The homology is but slightly obscured

by the fact that the cross vein  $r-m$  is in direct line with the distal part of  $R_5$ , making the latter appear to arise from  $M$ . It is suggested that the same interpretation should be made in the case of the Molannidae and the Leptoceridae. In these families  $R_5$  has more definitely assumed relations with  $M$ , with which vein its distal part may be wholly fused. This interpretation is based not only on comparison with *Helicopsyche*, but also upon the fact that it leaves the "corneous point" within cell  $R_4$ , where it occurs in all other families if it occurs at all. The venation of the hind wings of these forms is similarly interpreted.

LUCY W. SMITH, Mt. Holyoke College: *Mating and Egg-laying Habits of Perla immarginata*.

In introduction the paper gives a general description of the method of keeping adult stoneflies under observation in captivity, and of handling their eggs. This is followed by a detailed account of the genital armature, copulation and egg-laying habits of a single species, *Perla immarginata*.

ALVAH PETERSON, University of Illinois: *Head and Mouth Parts of Cephalothrips yuccae*.

A preliminary report on the asymmetry of the mouth-parts of Thysanoptera. A detailed description of the anatomy of the mouth-parts and head capsule of *Cephalothrips yuccae*, a species belonging to the suborder Tubulifera, was given. Numerous details and parts heretofore undescribed as to mandibles, hypopharynx, epipharynx, arms of tentorium, etc., were shown. Similar observations were made on *Anthothrips verbasci* in order to verify results found in *Cephalothrips yuccae*.

Comparing the work done by H. Garman on *Limothrips cerealium*, a species of Terebrantia, with the work done by Muir and Kershaw on a species of Tubulifera, a difference in interpretation exists as to whether the asymmetrical parts are mandibles or maxillae. Muir and Kershaw interpret the asymmetrical parts as maxillae. Observations made by the writer on two species of Tubulifera verifies their position in general. The writer expects to continue his observations on species of the suborder Terebrantia to determine if possible whether the interpretation of H. Garman is correct or not.

J. E. WOODSDALEK, University of Wisconsin: *Life History and Habits of Trogoderma tarsale*, a Museum Pest. Read by title.

LEONARD HASEMAN, University of Missouri: *Life Cycle and Development of the Tarnished Plant Bug, Lygus pratensis* Linn. Presented by the secretary.

Owing to the very serious injury to peach and pear in the early spring which seemed to be due to the work of the tarnished plant-bug, the writer has undertaken a careful study of the life cycle, habits and development of this insect. The work has been carried through the late summer and fall months and will be continued throughout the following spring and summer.

In this work it has been found that the tarnished plant-bug breeds largely upon various flowering weeds, such as wild asters, daisies and mare's tail (*Erigeron canadensis*). The tarnished plant-bug deposits its eggs in the blossoms of the host plant and not in the tissue of the leaves or stems. These eggs hatch in from five to seven days and the insect passes through five distinct nymphal stages in its development in the place of four, as other writers have maintained. The insect remains in each nymphal stage for about the same length of time and completes its growth in from thirty to thirty-five days.

VICTOR E. SHELFORD, University of Chicago: *The Ontogeny of Elytral Pigmentation in Cicindela*.

The pigment develops in the form of a faint pattern, somewhat variable, but with certain lighter areas occurring in the same general position in several species. These lighter areas lie between the tracheæ and in certain transverse bands; their position corresponds to those of certain white markings of Ethiopian and Oriental species.

N. L. PARTRIDGE, University of Illinois: *The Tracheation of the Pupal Wings of some Saturnians*.

A method of preparing permanent mounts of lepidopterous pupal wings was described. The pupal wings were removed in the customary manner and the specimens secured, floated upon clean water to straighten the wings and remove any dirt which might adhere to them. Then they were placed on a clean, untreated glass slide, smoothed and allowed to dry, without further treatment. The result was a transparent mount showing all the tracheoles as well as the tracheæ. Some of these mounts were used as lantern slides, giving clear images on the screen.

It was shown that a greater amount of variation was found in the pupal wings than in the adult wings. The homologies between the tracheæ and veins, of the specimens shown, was indicated.

L. B. WALTON, Kenyon College: *Studies on the Mouth-parts of Rhyarobia maderiæ (Blattidæ)*

with a consideration of the Homologies existing between the Appendages of the Hexapoda.

The question as to the homologies existing among the paired appendages of the Hexapoda has received attention from various investigators, and in particular from Hansen, Heymons, Börner, Verhoeff and Escherig, none of whom, however, have progressed far toward a satisfactory solution of the problem. In general it has been accepted that the stipes and mentum corresponded to the thoracic and abdominal coxæ while the maxillary and labial palpi were equivalent to the trochanter, femur, etc., of the functional leg.

Studies on *Rhyparobia maderæ*, the "giant cockroach" from Panama, particularly of 10 mm. and 12 mm. embryos, as well as other investigations in connection with the appendages of the Thysanura, make it evident that the typical appendage (mouth parts, thoracic, abdominal, caudal) of the Hexapoda consists of seven definite areas best represented by the maxillæ with the galea, lacinia, ectostipe,<sup>1</sup> endostipe, ectocardo, endocardo and palpus. Furthermore, the palpus should be homologized with the stylus of the thoracic and abdominal coxæ and not with the functional leg, inasmuch as both palpus and stylus are appendages of homodynamous areas (ectostipe, ectomentum, meron) while the leg is an appendage of the area (endocoxa) corresponding to the endostipes.

The facts noted suggest the origin of the biramous appendage of the Hexapoda directly from the parapodium of the Polychèta, the notopodium and neuropodium arising in connection with the dorsal and ventral bundles of setæ and corresponding to the outer (ectal) and inner (endal) groups of sclerites as outlined above. It would thus appear that the Arthropoda are a polyphyletic group, and that the relationship between the appendages of the Hexapoda and Crustacea is a more remote one than generally accepted in connection with the studies of Hansen and Börner.

The historical development of the problem as well as the presentation of the facts which would seem to establish the views here advanced, will appear in the completed paper, of which this is a partial summary.

JAMES ZETEK, Sanitary Commission Canal Zone:

<sup>1</sup>The prefixes "ecto" and "endo" have been utilized in an attempt to establish a better nomenclature, while minor changes have been made in the terminology of older parts, e. g., "ectostipes" is a more cumbersome term than "ectostipe."

*Determining the Flight of Mosquitoes.* Read by title.

WILLIAM A. RILEY, Cornell University: *Some Sources of Laboratory Material for Work on the Relation of Insects to Disease.*

The demand for at least elementary courses on the relation of insects to disease brings up the question as to available laboratory material. There is comparatively little difficulty in obtaining the parasitic mites, ticks, lice, house-flies, mosquitoes and fleas in their various stages, but it is usually assumed that most of the pathogenic Protozoa are tropical species and that nothing can be substituted for them in laboratory work. As a matter of fact, a number of insect-borne Protozoa and worms occur in this country and, together with other blood parasites whose life-history is less better known, are available for laboratory work. The species discussed were *Trypanosoma lewisi*, a widely distributed parasite of brown rats; *Trypanosoma rotatorium* from the frog; the related *Crithidia* from the "sheep tick"; *Herpetomonas* from the house-fly; *Monocystis* from the seminal vesicles of the earthworm as introductory to the study of the Hæmosporidia; *Lankesterella ranarum*, *Hæmogregarina* sp.; *Proteosoma*, *Halteridium*, *Babesia hilaria* in the blood of the crow and English sparrow, and *Dipylidium caninum*, the double-spored tapeworm of dogs, cats and man.

Y. H. TSOU and S. B. TRACKER, University of Illinois: *The Homology of the Body Setæ of Lepidopterous Larvæ.*

This paper consisted (1) of a statement of the difficulties involved in homologizing the body setæ of these larvæ, (2) of a consideration of the serial homology of the setæ of the different segments and (3) of the specific homology in the larger groups. Greek letters were employed to designate the setæ in order to obviate the confusion which has arisen from the use of numbers in different ways by different authors. The prothorax of *Hepialus* was shown to represent the primitive arrangement of setæ and was used as a type for determining the homology of the setæ on the different segments. The authors had studied many species and gave figures of four: *Hepialus lectus* and *H. humuli* of the Jugate, *Pseudanophora arcanella* of the Tineidæ and *Mamestra picta* of the Noctuidæ. Each of these was compared with the type, segment for segment. This is the first time the setæ of the prothorax have been homologized with those of the other segments.

ANNA H. MORGAN, Mt. Holyoke College: *Eggs and Egg-laying of May-flies.*

This study of May-fly eggs was made to determine the relative fecundity of different species. This led to the study of a series of elaborate sculpturings found upon the chorion. In several species the chorion bears long thread-like extensions which terminate in viscid spheres or disks. These seem to help buoy up the eggs. Threads two and three inches long were found. In nature these threads are probably entangled in sticks and vegetation and this prevents the eggs from being covered by silt. In the ovaries of half-grown nymphs these structures are well defined and are of aid in connecting up the life histories where rearing is impossible.

HERBERT OSBORN, Ohio State University: *Notes on Cicadidae with Especial Reference to the Ohio Species.*

Cicadas constitute a conspicuous element in insect fauna and their relation to varied forest conditions is discussed especially for the species occurring in Ohio. The origin and function of the tympanal organs present problems for study and the suggestion is made that this structure is primarily a secondary sexual character functioning in sexual excitation and only incidentally a sound-producing organ.

FRANK E. LUTZ, American Museum of Natural History: *On the Biology of Drosophila ampelophila.*

This insect is remarkably useful in laboratory work, since it can be kept going throughout the year on bananas as food and its short life-cycle (about ten days to two weeks) enables one to get a large number of generations. Sexual difference characterizes the insect. Not only do the sexes differ in adult color and structure, but they differ in the duration of the immature stages, in their reactions to light and the age at death.

E. P. FELT, State Entomologist, New York: *Observations on the Biology of a Blow-fly and a Flesh-fly.*

A study of *Phormia regina* Meign. and *Sarcophaga georgina* Wied. was undertaken primarily for the purpose of obtaining data which could be used as a basis for estimating the period a human body had laid exposed to the elements in mid-summer. Our knowledge of these two species is summarized and original data are given on the habits and duration of the various stages under known climatic conditions. The egg of *Phormia* and the three larval stages and puparium of both

species are described and a bibliography of each appended.

EDITH M. PATCH and WILLIAM C. WOODS, Maine Agricultural Experiment Station: *A Study in Antennal Variation.* Read by title.

ALEX. D. MACGILLIVRAY, University of Illinois: *Propharynx and Hypopharynx.*

The pharynx after entering the occipital foramen makes a distinct bend toward the mouth. In the region of the clypeus it divides transversely, one half passes to the clypeo-labral side, the other half to the labial side of the mouth, while folds extend along each lateral margin and unite with the mandibles and maxillae. The name of propharynx is proposed for the portion lying adjacent to the clypeo-labral part of the mouth and hypopharynx is used for the portion lining the labial portion. The propharynx consists of three parts: frontal lobe, epipharynx and fulcrum. The frontal lobe is usually wanting in sucking insects, the epipharynx is modified into a tongue or piercing organ and the fulcrum into a cuticular supporting plate. In the muscids the epipharynx and fulcrum are located outside of the mouth, the proximal end of the fulcrum is attached to the distal margin of the labrum. The hypopharynx also consists of three parts: lingua, superlingua and pharangular sclerites.

T. L. WASHBURN, State Entomologist, Minnesota: *A Few Experiments in Photographing Living Insects.*

THOMAS J. HEADLEE, New Jersey Agricultural Experiment Station: *Some Facts Regarding the Influence of Temperature and Moisture Changes on the Rate of Insect Metabolism.*

While connected with the Kansas State Experiment Station at Manhattan, the writer found by subjection of different groups of the southern grain louse (*Toxoptera graminum* Rodani) to various constant temperatures under constant atmospheric moisture conditions and other groups to various constant percentages of relative humidity under constant temperature conditions: (1) that the rate of increase in metabolism for each 10° F. increase in temperature, starting at 50° F., decreases as the optimum temperature is approached, and that while the metabolism of degeneration becomes more rapid after the optimum is passed the rate of growth is retarded; (2) that a variation of from 60 to 62 per cent. in atmospheric moisture does not affect the rate of metabolism when the creatures have an abundant supply of succulent food.

Similar tests of the effect of temperature on the rate of metabolism in *Lysiphlebus trifici* Ashm. and of the effect of temperature and moisture on the rate of metabolism of the chinch bug (*Blissus leucopterus* Say) infected and uninfected by the chinch-bug fungus (*Sporotrichum globuliferum* Speg.) gave similar results.

J. T. ABBOTT, Washington University: *The Strigil in Corixidae and its Probable Function*. Read by title.

EDNA MOSHER, University of Illinois: *The Anatomy of some Lepidopterous Pupæ*. (Presented by Mr. Alvah Peterson.)

Figures of pupæ of three species were shown; also figures of the pupæ with the cases dissected away so as to show the parts underneath. Considerable difficulty has been encountered in homologizing the pupal structures from the external appearance, particularly in the case of the fixed parts of the head and the appendages of the head and thorax. The leg cases were shown to be a frequent source of error. Instead of showing externally only the cases for the tibiae and tarsi, as Seudder claims is the case in the butterflies, certain forms show the femur cases and either the whole or part of the coxal cases in certain pairs of legs. What Packard calls the paraclypeal pieces, were shown in these forms to contain functionless mandibles which had their distal margins toothed in the case of *Lymantria*.

This detailed anatomical study is to be made the basis for a phylogenetic and taxonomic arrangement of the Lepidoptera based on an examination of the characters of the pupæ.

CHARLES K. BRAIN, Ohio State University: *Some Anatomical Studies of Stomoxys calcitrans* Lin. (Introduced by Professor Herbert Osborn.)

The external mouth-parts and digestive system of both sexes of this species are identical in structure, and both sexes suck blood. The external mouth-parts consist of maxillary palpi and proboscis; the latter consisting of labrum, hypopharynx and the labium.

The digestive system consists of proboscis, pharynx, œsophagus, proventriculus, intestine, rectum and the appendages, viz., salivary glands, sucking stomach and Malpighian tubes. The two Malpighian tubules of the left Malpighian tube have much thickened ends, which lie dorsally. Those of the right side have no such thickened ends. The male reproductive organs consist of a pair of spherical testes which appear orange-colored in dissections, owing to their pigmented

sacs, their ducts leading into the common vesicula seminalis, the ejaculatory duct and the penis.

The female reproductive organs consist of the ovaries, oviducts, uterus and ovipositor, with the appendages, the uterine glands and the receptacula seminis.

S. W. BILSING, Ohio State University: *Observations on the Food of Spiders*. (Introduced by Professor Herbert Osborn.)

Spiders are known to feed upon insects, but exact records of kind and quantity of food for particular species are very meager. Extended observations and records were made during the summer and fall of 1912 and data from some of these are presented. As an example of the records given, grasshoppers constituted 39 per cent. of the food of *Miranda aurantia*, 59 per cent. of the food of *Agalena nevai* and 22 per cent. of the food of *Aranea trifolium* during the period under observation.

HERBERT OSBORN, Ohio State University: *Observations on Insects of a Lake Beach*.

The insect fauna of the Cedar Point Beach of Lake Erie is discussed with reference to its derivation and adaptation for the conditions presented. The insect drift, the migrant and the resident members of the association are separated and records of species in each group given.

C. H. TYLER-TOWNSEND, Government Entomologist of Peru: *The Species-Status and the Species-Concept*. Read by title.

C. H. TYLER-TOWNSEND, Government Entomologist, Peru: *A New Application of Taxonomic Principles*. Read by title.

The annual public address of the society was given on Wednesday evening, January 1 in the auditorium of the Normal School by:

DR. PHILIP P. CALVERT, University of Pennsylvania: *An Entomologist in Costa Rica*.

There was briefly recounted certain physical and meteorological features of that country which render it very favorable for the study of the influence of these factors on the distribution and habits of plants and animals. A few localities, selected from those in which the speaker had worked during the year from May, 1909, to May, 1910, were described and their fruitfulness illustrated by some of the discoveries made of the habits and life histories of the Odonata (dragonflies) obtained therein.

The following officers were elected for the ensuing year:

President—C. J. S. Bethune.

First Vice-president—Philip P. Calvert.

Second Vice-president—W. M. Marshall.

Secretary-Treasurer—Alex. D. MacGillivray.

Additional Members of the Executive Committee

—Herbert Osborn, C. P. Gillette, V. L. Kellogg,  
J. G. Needham, C. T. Brues and Nathan Banks.

Member of Committee on Nomenclature for  
three years—E. P. Felt.

ALEX. D. MACGILLIVRAY,

Secretary

## SOCIETIES AND ACADEMIES

### THE BOTANICAL SOCIETY OF WASHINGTON

The eighty-fifth regular meeting of the Botanical Society of Washington was held at the Cosmos Club, Tuesday evening, January 7, 1913.

The following scientific program was presented:  
DR. DAVID GRIFFITHS: *Performances in Species of Opuntia*. (Illustrated with lantern slides.)

This paper will be published in the near future as a bulletin of the Bureau of Plant Industry.

MR. J. B. NORTON: *Some Interesting Facts Concerning the Genus Asparagus*. (Illustrated with lantern slides.)

This paper gave a review of the interesting features connected with the work of breeding a rust-resistant variety of asparagus. *Asparagus officinalis* has never been found to be completely immune to the attacks of its rust, *Puccinia asparagi*. Plants nearly immune to the destructive summer stages show no resistance to the æcidial stage of the fungus. Resistance seems to be due to morphological causes. Related species are attacked by the rust, but the members of other sections of the genus seem immune. The genus *Asparagus* and its relatives are entirely limited to the old world, the majority being African. A study is being made of the relationships of this group and many new characters based on the manner of growth, roots, stems, leaf scales, cladodes, etc., have been found. The arrangement of the stomata on the cladodes is very characteristic in the various groups. The old genus *Asparagus* contains several very distinct groups of species entitled to generic rank.

Only one hybrid form of known parentage has been secured, a cross between *A. officinalis* and *A. davuricus*. Many other combinations have failed to produce seed. *Asparagus* grows rapidly—some species average nine inches per day. The seed germination takes from 12 days with *officinalis* to 60 or more days with some African spe-

cies. Several new ornamental forms were described.

C. L. SHEAR,

Corresponding Secretary

### THE TORREY BOTANICAL CLUB

THE meeting of November 12, 1912, was held at the American Museum of Natural History. President Burgess presided.

The announced scientific program consisted of an illustrated lecture by Dr. J. J. Levison on "Tree Problems of our City."

THE meeting of November 27, 1912, was held in the laboratory of the New York Botanical Garden. Vice-president Barnhart presided.

The first paper was by Dr. W. A. Murrill, on "The Polypores of the Adirondacks." This paper has been published in full in the *Journal of the New York Botanical Garden*, 13: 174-178, November, 1912.

The second number was given by Dr. A. B. Stout. The subject of his discussion was "The Distribution of Tissues in the Root Tip of *Carex aquatilis*." Several photomicrographs of sections of root tips were exhibited, and drawings were made to illustrate particular features in the arrangement of the tissues.

THE meeting of December 10, 1912, was held at the American Museum of Natural History. President Burgess presided.

On the motion of Dr. Southwick the treasurer was authorized to draw an order for the sum of twenty dollars in favor of Dr. William Mansfield to cover the dues as the representative of the club to the council of the New York Academy of Sciences.

The paper of the evening was on "Diatoms," by Dr. Marshall A. Howe. It was a semi-popular account of the principal structural and morphological features of diatoms, their distribution and habitat, their geological interest and importance, the various economic uses of diatomaceous earths, etc. The talk was illustrated by about seventy-five lantern slides from the collection of the late Charles F. Cox. Many of the photographs shown were made under high powers of magnification and they brought out with much distinctness the secondary markings and other minute structural details of the walls of various types of diatoms.

B. O. DODGE,

Secretary

NEW SERIES  
VOL. XXXVII. No. 948

FRIDAY, FEBRUARY 28, 1913

SINGLE COPIES, 15 Cts.  
ANNUAL SUBSCRIPTION, \$5.00

The intimate alliance between the  
**CARL ZEISS OPTICAL WORKS**  
and the  
**BAUSCH & LOMB OPTICAL CO.**

is a distinct boon to the American user of optical instruments. Not only does it mean an interchange in ideas---the union of scientific and productive effort---but it now affords a ready source of supply in America of the different Zeiss lines in most general demand.

To effect this we have imported a **stock of Zeiss Products**, not only for our home office but for each of our branches, to which we invite the personal inspection of all interested. From this stock we are prepared to make prompt shipments at duty paid prices.

We are also glad to serve customers at any time in importing Zeiss products as promptly as possible at **duty free prices**. Zeiss literature on any of the lines will be sent free upon request.

**Bausch & Lomb Optical Co.**

JUST ISSUED

## PRECISION OF MEASUREMENTS AND GRAPHICAL METHODS

By H. M. GOODWIN, PH.D., Professor of Physics, Massachusetts Institute of Technology. 104 pages, 6x9. \$1.25 (6/3) net, postpaid.

This textbook is designed for a brief course, correlating closely the class room and laboratory work. **Part I** discusses Classification of Measurements, Precision Discussion of Direct Measurements, Deviation and Precision Measures, Weights and Weighted Mean, Criterion for Rejecting Observations, Computation Rules and Significant Figures, Precision Discussion of Indirect Measurements. **Part II**, Graphical Methods, contains specific directions for constructing graphs and general directions for obtaining the functional relationship between two variables. **Part III** contains the solution of a few illustrative problems together with 79 questions and problems for class use. The appendix gives several useful tables.

### Palmer—THE THEORY OF MEASUREMENTS

By A. DE FOREST PALMER, PH.D., Assoc. Prof. of Physics, Brown Univ. 248 pp. Illus. \$2.50 (10/6) net, postpaid. A discussion of principles and methods.

### Northrup—METHODS OF MEASURING ELECTRICAL RESISTANCE

By EDWIN F. NORTHRUP, PH.D. 389 pp. Illus. \$4.00 (17s) net, postpaid. An authoritative treatise describing methods, simple measurements, details of instruments, etc.

## THE INTERNATIONAL CHEMICAL SERIES

HENRY P. TALBOT, PH.D., Consulting Editor

The first volumes in this series have had a gratifying reception. They have been approved and adopted by several institutions.

### Norris—THE PRINCIPLES OF ORGANIC CHEMISTRY

By JAMES F. NORRIS, PH.D. Professor of Chemistry, Simmons College, Boston. 570 pp., 5½x8. Illustrated. \$2.50 (10/6) net, postpaid.

### Cady—INORGANIC CHEMISTRY

By HAMILTON PERKINS CADY, A.B., PH.D. Professor of Chemistry, University of Kansas. 629 pp., 5½x8. Illustrated. \$2.50 (10/6) net, postpaid.

### STUDY OF MINERALS

A Combined Text Book and Pocket Manual

By AUSTIN FLINT ROGERS, PH.D., Assoc. Prof., Leland Stanford Univ. 522 pp., 5x7½. Flexible leather. \$3.50 (15s) net, postpaid.

### PETROGRAPHIC METHODS

By E. WEINSCHENK, Trans. by ROBT. W. CLARK, Instructor in Petrography, Univ. of Michigan. 396 pp. 371 Illus. \$3.50 (15s) net, postpaid.

## THE CARNEGIE INSTITUTION OF WASHINGTON<sup>1</sup>

### PRESENT STATUS OF THE INSTITUTION

ALTHOUGH the institution is quite young and must be considered as still, to some extent, in its formative stages, this first year of the second decade of its history marks an epoch worthy of something more than passing notice. During this year, to a degree hitherto impracticable, there has been opportunity for an objective view of the meaning of the extensive and varied experience, acquired by the institution, of the principles which have guided its development, and of the limitations, difficulties and dangers which may beset its future progress. During this year also, to a greater degree than hitherto, have appeared evidences from widely divergent sources of an increasing public tendency to take an objective view of the plan, scope, organization and development of the institution and to measure its efficiency by the results of its investigations already published or under way. From these objective views it appears that, in spite of a great diversity of opinion as to what research is and how it should be carried on (a diversity which seems destined to continue indefinitely), there is now a consensus of opinion that the institution has established its position and demonstrated the practicability of the conduct of effective research in establishments wholly devoted thereto, separate and apart from other establishments whose functions are primarily and commendably agricultural, charitable, com-

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

<sup>1</sup> Extracts from the report of the president for the year ending October 31, 1912.

mercial, educational, governmental, political, religious or social. Thus, in general, it may be said that, as regards internal and external relations and interrelations, the institution in its chosen field of activity has now reached a status approximating to stability of adjustment, wherein definiteness of aim, continuity of effort and concentration of energy and resources may be more productively applied than heretofore.

But while the work proper of the institution, namely, work of research, is in a satisfactory condition, as much may not be said of the adventitious work incident especially to the administrative office. For although this latter work is sometimes instructive and occasionally useful, it is generally fruitless and often excessively wasteful of time and energy which might otherwise be turned to better account. This work involves a vast correspondence concerning an endless variety of subjects and particularly concerning an endless variety of objects for which funds might be spent. In its higher phases it is the work of an intelligence office and may be accepted as a not unworthy though unintended function of the institution; in its lower phases it is in need of curtailment in the interests alike of all concerned.

The time for a detailed, or even summary, account of this highly complex and to some extent psychologically important experience has not yet arrived. Such an account must be left to historians interested in the evolution of institutions or to analysts, like De Morgan, in search of a mine of materials for a new "Budget of Paradoxes." It is plainly the part of wisdom, however, not to wait for verdicts of the historian and the analyst, but to make use of such inductions as may be safely drawn, not only from the experience just referred to, but also from that gained in the work proper to the institution. Most

of the theories, ideas and sentiments involved are subject to the tests of statistical treatment which determine with sufficient accuracy the more fruitful methods of procedure. Of the many inductions which may be thus drawn out of the experience of the institution a few may be here set down as indicative of existing conditions and tendencies.

It is in evidence—

1. That there are the amplest room and the amplest opportunity for research establishments without danger of encroachment on establishments founded for other purposes; that it is not difficult for the institution to find appropriate ways in which to apply its income; that there are, in fact, in plain sight, ten times as many worthy, practicable subjects of research and ten times as many worthy investigators as the income of the institution can advantageously subsidize.

2. That there are many investigations of such magnitude and difficulty that they can not be carried on economically and effectively except by men untrammelled by other occupations. The common notion that research demands only a portion of one's leisure from more absorbing duties tends to turn the course of evolution backwards and to land us in the amateurism and the dilettantism wherein science finds its beginnings.

3. That it is inimical alike to the interests of society and to those of the institution to look upon it as a mere disbursing agency designed to meet emergencies or to supply deficiencies of other institutions and of individuals. The widely spread impressions that the income of the institution is sufficient to meet the aggregate of such emergencies and deficiencies, and that the institution can undertake to play the rôle of a special providence and thus anticipate the collective needs of deserving

individuals and organizations, have no foundations in fact.

4. That while there may be wisdom in a multitude of counsels, it becomes increasingly difficult of access as the multitude enlarges and is generally obscured, if not hidden, by a conflict of opinions. The current popular impression that discoveries and advances may be favorably promoted by the patient examination of a vast aggregate of miscellaneous suggestions is a fallacy abundantly demonstrated by the probably unequaled data available to the institution.

5. That it is neither practicable nor advantageous for the institution to undertake to perfect inventions, to secure letters patent for them, to defend inventors in suits at law, or to exploit successful inventions. The objects of the inventor are primarily egoistic and hence secretive; the objects of the institution are primarily altruistic and hence non-secretive; their divergence is so great as to render them mutually exclusive under existing conditions. The distinction between invention and investigation is rarely understood and is not always easily drawn. They are indeed closely allied; for the inventor is often compelled to make investigations and the investigator is often compelled to devise inventions. It should be said also that the egoism of the inventor which leads him to secretiveness and to seek state privileges through patent rights has its correlative in the desire of the investigator to secure priority of discovery and publication. The distinction is one of reversed attitudes and objects. The inventor is primarily interested in direct personal benefits which may come from the application of facts and principles in the perfection of useful devices, machines and processes. The investigator is primarily interested in the discovery of facts and principles which may

be given freely to the world without expectation of immediate application or hope of direct personal benefit. It is claimed, however, that the party of the second part to be considered in all such matters, namely, society, is in general disproportionately the gainer over both the inventor and the investigator. The extensive evidence on this subject acquired by the institution shows clearly that the indirect advantages to the investigator arising from his altruism are generally much greater than the direct advantages to the inventor arising from his egoism. This evidence is, indeed, so convincing as to suggest the desirability, at some future date, of the organization of a department devoted to inventions, which, instead of being protected by patent rights should be protected, if at all, against them. It is plain, in fact, that if society could make use of knowledge now available the labors of the expert inventor could become far more fruitful and far more satisfactory to him than they are at present.

#### RÉSUMÉ OF INVESTIGATIONS OF THE YEAR *Departments of Research*

It is now nine years since the earliest of the departments of research established by the institution were authorized and six years since the latest of them was authorized. This lapse of time has now fully demonstrated that these departments are all engaged in enterprises which, by reason of their magnitudes, were unlikely to be carried out under other auspices. They have grown very rapidly and have become highly productive. All of them tend continually, and in many respects properly, to expand as their several fields of investigation are developed. They thus tend constantly to press closely upon the available income of the institution and hence to become a source of concern by reason of their highly commendable progress. But the

remedy for this paradox does not lie alone in increased expenditures; to an equal extent, at least, it lies in increased efficiency under slowly increasing, or even stationary or decreasing, expenditures. It is a special duty of the man of science to show how more and better work can be done at less cost than has been practicable to his predecessors.

Although these departments of investigation, like the institution as a whole, have fallen short of popular expectations in the rapidity of their growth, it now appears plain, in the light of their actual experience, that this growth has been somewhat too rapid for safety. Along with this rapid growth and with the signal success of these departments in their several fields of research, there are now coming also numerous requests for cooperation with other organizations and with individuals. But while these requests are in general gratifying and often praiseworthy, they present some obvious hazards. There is need, therefore, of constant caution against the dangers of undue expansion and affiliation which lead to dissipation of effort and resources. It should be kept in mind that concentration on definitely limited programs, continuity of effort and energetic assiduity are the factors most essential to progress in the domain of research.

The plan referred to a year ago, of inviting one or two eminent specialists to become associated with each of the departments for limited periods of time, has thus far worked quite advantageously and promises to become increasingly fruitful. Eight such specialists have been connected with the departments during the past year by direct appointment of the executive committee, with varying compensations, as shown in the financial section of this report. Some other research associates have served without compensation and several

collaborators have also partaken in departmental investigations or availed themselves of departmental facilities without direct expense to the institution.

As usual, in the president's report, reference must be made to the departmental reports, to be published in full in the current year book, for comprehensive accounts of departmental investigations, publications and plans for future activities, as well as for accounts of the work of departmental associates and collaborators. Only the briefest summaries, indicating some of the salient features of these accounts, are attempted in the following paragraphs.

#### *Department of Botanical Research*

The geographical range of the work of this department, which centers in the Desert Laboratory at Tucson, Arizona, has been extended during the past year to include certain portions of the deserts of northern Africa. Thus Dr. Cannon spent the late autumn and early winter of 1911-12 in the deserts of Algeria, while Director MacDougal and his engineer, Mr. Sykes, spent a good share of the winter of 1911-12 in the Lybian deserts. These expeditions enabled the department to acquire extensive information for comparative studies of desert areas, and Dr. Cannon's report on the results of the earlier expedition has been already received for publication.

Studies have been continued also at the Desert Laboratory, at the Carmel Laboratory on the California coast, at Salton Sea, and at various substations where observations are made on the phenomena presented by plants under strikingly varying conditions. The desiccation of the Salton Sea now under observation presents many instructive conditions which are being carefully studied in their climatic, biological and physical aspects. It will be practi-

cable, therefore, in the course of a few years, to furnish something like a detailed history of this remarkable basin, which has now been carefully studied at intervals since its discovery in 1854 by the late Professor N. P. Blake.

One of the most important investigations undertaken during the past year is that of a comprehensive study of the large and highly diversified family of cactus plants. Through the cooperation of Professor N. L. Britton, director of the New York Botanical Garden, and Dr. J. N. Rose, of the staff of the Smithsonian Institution, who have been appointed research associates, it will be practicable, by aid of the facilities of the department, to produce a monographic study of these typical desert plants.

Several volunteer associates and collaborators of the department have participated in departmental researches and contributed to the progress attained therein. Upwards of twenty individuals have taken part in one or more phases of this work.

#### *Department of Experimental Evolution*

The advances made by this department during the past year have been chiefly along the lines of studies in cytology, in the chemistry of pigmentation, in the factors of mutation, and in the problems of human heredity. These studies have been carried on by aid of experiments with plants and animals and by aid of rapidly accumulating statistical data concerning human traits and their transmission through successive generations. The director has been able to give much of his time to studies in human heredity by reason of his connection with the Eugenics Record Office, whose work has been liberally supported by Mrs. E. H. Harriman and by Mr. John D. Rockefeller. The experiments of the department proper with plants and animals are thus supplemented

very advantageously by the extensive information already acquired by the Eugenics Record Office in respect to human heredity.

Very interesting chemical studies have been carried on by Dr. Gortner, a member of the staff, in respect to the chemical nature of pigments which determine color characteristics, especially of the plumage in birds, of the wool in sheep, and of the skin in men.

Dr. Shull has continued his fertile studies into the heredity of plants, including further investigations into the connection between heredity and environment in the case of corn. These further studies confirm his earlier conclusions and show also that the hereditary traits of different strains are maintained irrespective of environmental influences.

The director calls attention to the need of his department for additional buildings and equipments. A recommendation with respect to this need will be found in a subsequent part of this report.

#### *Department of Economics and Sociology*

According to the report of Professor Henry W. Farnam, chairman, the work of this department has now reached such a stage of advancement that the time of its completion depends mainly on the amount of leisure the collaborators may obtain in the near future for consecutive attention to their several contributions to the "Economic History of the United States." By aid of the special appropriation for payment of salaries (made by the board of trustees a year ago), it is now practicable for some of the collaborators to devote part of their time and attention consecutively to this work, and two or three of them will doubtless be able to give at least half-time under this plan during the ensuing year.

The present status of the investigations of the several divisions of the department is set forth in detail by the chairman in his report.

The attention of the trustees is especially invited to a paragraph in Professor Farnam's report calling attention to the desirability of a more permanent organization of this department before its present program of research is completed. He recommends an organization similar to that of other departments of the institution, which would involve the appointment of a salaried director and a permanent staff. The experience of the institution leaves no doubt as to the wisdom of this recommendation on the score of continuity and efficiency for this as well as for other departments of the institution. Further reference to this subject will be made in the budget section of this report.

#### *Geophysical Laboratory*

The list of twenty-six publications which have emanated from the geophysical laboratory during the past year, and which are briefly reviewed by the director in his annual report, furnishes the best index of the activity of this establishment. Two specially noteworthy publications of the laboratory have been issued during the year by the institution, namely, No. 157, "High Temperature Gas Thermometry," and No. 158, "The Methods of Petrographic-Microscopic Research." The purpose of the first of these was to give an account of the apparatus and methods for accurate measurement of the critical temperatures incident to mineral combinations; and the object of the second is to place, so far as practicable, microscopic study of minerals upon a quantitative basis. Attention has hitherto been called to this characteristic feature of the investigations of the geophysical laboratory,

which is a characteristic feature of all of the advancing sciences. The work already accomplished demonstrates the practicability of achieving this object for the science of mineralogy. This advance requires that special attention be given to accurate measurements of high temperatures and high pressures, as well as to their simultaneous effects upon mineral constituents. Much study, therefore, continues to be given by the laboratory staff to the development of effective apparatus and technique for the measurements essential in this work.

Special attention is called in the director's report to extended studies on quartz and other forms of silica which is the most widely diffused ingredient in rock masses; to further experiments on the conditions of association of the three oxides, lime, alumina and silica, which in addition to being the commonest components of igneous rocks are also incidentally the three principal ingredients of the so-called Portland cement; to mineral sulphides, which are often of great economic importance; and to mineral and rock densities.

Perhaps the most interesting of the more recent investigations of the laboratory are those of the physics and chemistry of active volcanoes undertaken tentatively a year ago and pursued with very gratifying success during the past summer. It has proved practicable for members of the staff to descend into the crater of Kilauea and to collect considerable quantities of gas as it emerged from the liquid lavas of the crater. Specimens of gases were collected in glass tubes without contamination from the air, and these have been brought to the laboratory at Washington for detailed study. There seems little reason to doubt that the phenomena of vulcanism will be ultimately revealed by the methods, appa-

ratus and technique developed by the staff of the laboratory.

#### *Department of Historical Research*

Naturally a department devoted to historical research is chiefly concerned with the preparation of publications, and these latter for the department in question may be classified under the head of reports, aids and guides concerning materials relating to American history and under the head of textual publications of documents. Under the first head attention may be called to Professor Marion D. Learned's "Guide to the Manuscript Material relating to American History in German State Archives," No. 150 of the publications of the institution, which has appeared during the year. Two other volumes, namely, publication No. 90A, "Guide to the Materials for American History, to 1783, in the Public Record Office of Great Britain," and publication No. 163, "Guide to the Materials for the History of the United States in the Principal Archives of Mexico," of the institution are now in press. No. 90A has been somewhat delayed by reason of a reclassification to which large sections of the British Public Record Office were subjected after this work had been started by Professor Andrews. Another work in press by the department is Mr. David W. Parker's "Guide to the Materials for United States History in Canadian Archives," publication No. 172 of the institution.

Further progress is reported in respect to the work in charge of Mr. W. G. Leland, of the departmental staff, on materials for American history in the archives of Paris. Search has been made also in several other European cities for sources of American history. The director of the department spent the past summer in Europe and took occasion while there to devote special atten-

tion to the materials derivable from the five French-speaking cantons of Switzerland. Assistance has been rendered to the department during the year by several collaborators who have been called by the director to his aid in the preparation of the proposed atlas of historical geography of the United States, to which reference has been made in preceding reports.

Dr. Burnett, of the departmental staff, has been engaged chiefly upon the series of "Letters of Delegates to the Continental Congress," while Miss Davenport, also of the permanent staff, has been occupied nearly continuously in the collection of "European Treaties having a bearing on United States History." These documents promise to furnish much material hitherto inaccessible to students of American history.

#### *Department of Marine Biology*

The independent transportation facilities furnished by the staunch new vessel *Anton Dohrn*, and the repairs and improvements to the laboratory completed a year ago, have proved highly advantageous to the department of marine biology. By means of the *Anton Dohrn* the entire Gulf and West Indian region becomes open to investigation by the department. The director records with appreciation a gift to his fleet by Hon. John B. Henderson, of Washington, D. C., of a 23-foot, 6 horsepower launch, which has already proved a very useful adjunct in the diversified work of the department, since many different investigations are carried on simultaneously by different individuals at the laboratory headquarters.

During February and March of the current year the director established a temporary laboratory at Montego Bay, Jamaica, a region which sustains important biological relations to the vicinity of the

Tortugas group of islands. In addition to the director, nine other investigators pursued researches at this laboratory. In May the director and three collaborators visited the Bahamas, making a successful cruise of 570 miles with the *Anton Dohrn*. This expedition was of special aid to Messrs. Drew and Vaughan in their studies concerning oolite deposits and corals.

The director of the department has issued, as No. 162 of the publications of the institution, an additional volume of his series on the jelly-fishes of the world, the title of this volume being "Ctenophores of the Atlantic Coast of North America." Sixteen of his collaborators have presented papers for publication, which will furnish two more volumes of the "Researches from the Tortugas Laboratory."

#### *Department of Meridian Astrometry*

After the meridian instrument was brought back from the temporary observatory at San Luis, Argentina, to the Dudley Observatory at Albany, it was thoroughly reexamined to make certain that it had undergone no change on account of the relatively rough handling it necessarily received during this journey from Argentina to America. The reexamination was completed about the beginning of the present fiscal year and proved conclusively that the instrument had suffered no damage in any of its parts. Along with this good fortune to the department and to the Dudley Observatory, this instrument thus becomes noteworthy in the annals of astronomy, for no meridian circle has been so thoroughly proved to retain its stability under such a variety of varying conditions. After the preliminary tests referred to, observations with the instrument were begun on November 13, 1911, and have continued throughout the year, in accordance with the pro-

gram explained hitherto in the departmental reports.

In the meantime special attention has been given to the reduction of the meridian observations made at San Luis, Argentina. The determination of the two coordinates of stars from this work, namely, right ascension and declination, have proceeded simultaneously. The assignment of stellar magnitudes, however, must await the photometric determinations which have been made at San Luis since the meridian measurements were completed. Late advices from Mr. Zimmer, who has charge of this photometric work, announce that it will be completed by the end of the present calendar year, and he and his assistant are expected to return early next year.

The department reports with great regret the death, on November 19, 1911, by accidental drowning, of Mr. William Hunt, who served initially as Mr. Zimmer's assistant. Mr. Hunt was a young man of much promise, and his untimely loss was a source of shock to his colleagues and a cause of temporary delay to the photometric work.

Much attention has been given by the director of the department and by Mr. Benjamin Boss to studies of stellar motions for which the extensive data accumulated by the department are furnishing evidence. These studies and those made by the solar observatory of the institution, along with corresponding investigations in many other observatories, indicate that the progress of astronomy in the future is to be no less brilliant than it has been in the past.

The great quantity of priceless observational and derived data accumulated by the department rendered it imperative that special provision should be made for their safe storage. Accordingly the executive committee authorized the department to expend, from its last annual allotment, the

sum of \$2,000 for the construction of a fire-proof vault within the walls of the Dudley Observatory. This vault is now ready for occupancy and the records will be placed therein as soon as practicable.

### *Nutrition Laboratory*

Although investigations began immediately on the establishment of the nutrition laboratory five years ago, the novelty and importance of its field have called for continuous additions to its equipment, while added experience has suggested many improvements in the apparatus used. Thus during the past year two balconies have been added to the calorimeter laboratory, a treadmill designed to measure severe muscular work has been provided for a respiration chamber, and numerous modifications have been made in the calorimeters and respiration apparatus of the laboratory. More detailed studies of the bicycle ergometer, which has hitherto proved so useful in experiments on the metabolism of man during excessive muscular work, have rendered the apparatus available over a wider range of experimentation and with a higher degree of certainty than hitherto. The importance and success of the experiments already undertaken at the laboratory have created a widespread interest in the medical profession, and this interest has led to many cooperative investigations undertaken during the past year. The novel equipment of the laboratory has been the subject of much inquiry also, and many investigators from other laboratories have sought to secure copies of the apparatus used and to learn more of the technique developed by the director and his staff.

One of the most interesting of the many investigations under way during the year is that of the metabolism of a subject who underwent a prolonged fast, extending to thirty-one days without food, and who

drank only distilled water during this time. This investigation required the cooperation of a number of chemical, pathological and psychological experts. A detailed report on this elaborately observed experiment is at present in preparation. Another noteworthy investigation of the year is that on metabolism during severe muscular work, undertaken by Dr. E. P. Cathcart, of the University of Glasgow, who was a research associate of the institution during the winter of 1911-12. Amongst other important results of the latter research is the measure it affords of the mechanical efficiency of man. An account of this investigation is likewise in preparation for publication.

In addition to the numerous papers which have appeared in current journals from the laboratory, two volumes, Nos. 166 and 167 of the institution's series, have been issued during the year. The first of these is devoted to "The Composition of the Atmosphere with Special Reference to its Oxygen Content," and proves the remarkable fact of the essential constancy of this element in the atmosphere.

### *Department of Terrestrial Magnetism*

Highly effective progress has been made by this department during the past year in its magnetic survey of the globe. By means of the non-magnetic ship *Carnegie* it is now easier to make a magnetic survey of the ocean areas than of the land areas, for the former are now more readily accessible than the latter. At the end of the preceding fiscal year the *Carnegie* was at Batavia, Java. On November 21, 1911, she set sail for an additional circuit of the Indian Ocean, whence she proceeded to Manila, Philippine Islands, where she arrived February 3, 1912. From Manila she proceeded to Suva, thence to Tahiti, and is now en route to Coronel, Chili. During the fiscal year she traversed about 28,000

miles. Her courses are arranged to intersect as frequently as possible her own previous tracks, those of the *Galilee* and those of previous expeditions on which magnetic elements were observed. Valuable checks on the determinations of these elements are thus secured, and in case of considerable intervals between the dates of different determinations, data for secular variation of the magnetic elements are also obtained. As related in the report of a year ago, unexpectedly large errors were found in the best magnetic charts of the Indian Ocean and for some parts of the Pacific Ocean. In order that corrections may be speedily applied to such charts the results of the cruises of the *Carnegie* are promptly made known to the principal hydrographic offices of the world. It is expected that the *Carnegie* will complete her present circumnavigation of the world near the end of the next fiscal year.

Observations have been continued simultaneously on land areas, embracing portions of five continents and about twenty different countries. Many noteworthy series of trancontinental stations have now been completed. Of these, one extending across the entire continent of South America, beginning at Para, at the mouth of the Amazon, and extending to Callao on the Pacific coast, by way of the Amazon and Ucayali rivers and Lima, has been finished during the past year.

The first volume of researches of the department, giving the results of land observations from the time of its establishment in 1905 down to the end of the year 1910, is now in press. The final computations of the ocean observations made during the various cruises of the *Galilee* and the *Carnegie* are also well advanced for a second volume. Many improvements in instrumental appliances have been made during the year in response to needs and

suggestions arising from the extensive experience of the department on land and sea. One of the most important of the new appliances devised is that called an "earth inductor," which permits the measurement of the dip of the magnetic needle with increased precision and decreased labor over devices previously used. An attempt is now being made to apply this apparatus, which has proved completely successful on land, to the determination of dips on the *Carnegie*.

### *Solar Observatory*

The past year has been one of minimum sun-spot activity; but effective progress has been made in many other branches of solar and stellar research undertaken by the observatory. The wide range of this work may be indicated by the fact that the results of the investigations of the year are summarized by the director under thirty-five different heads. The new tower telescope has been completed and important auxiliary apparatus has been added to the equipment of the 60-inch reflector. A fire-proof office building, which will afford adequate quarters for the staff and safety for the original records and photographic plates of the observatory, has been constructed and made ready for occupancy during the year.

The 150-foot tower telescope with its spectrograph and spectroheliograph has been tested and found to be quite up to expectations. The 60-inch reflector has proved increasingly effective in the wide variety of work undertaken with it. Between forty and fifty new spectroscopic double stars have been found; and amongst the many stars whose radial velocities have been measured is one which surpasses all other hitherto observed, its velocity being about 150 miles per second.

Two eminent research associates, namely,

Professor Kapteyn, of Groningen, and Professor Störmer, of Christiania, have taken part in the work of the observatory during the year. Professor Kapteyn, who has served in this capacity for several years previously, has been of great service to the department, especially in the planning of a program of work with the 60-inch reflector, so that it may yield a maximum return alike for problems of stellar distribution and stellar development. Professor Störmer, who is one of the highest authorities concerning auroras, has sought to determine especially the connection of these phenomena with the sun. Of their connection with the sun and with the earth's magnetism there is little doubt, and the recent demonstration of the atomicity of matter in general and the atomic nature of electricity in particular may be confidently expected to lead to distinct advances in our knowledge of these phenomena in the near future.

The laborious task of shaping and testing the glass disk for the proposed 100-inch telescope has proved a disappointment in showing that this disk, which was accepted provisionally from the makers several years ago, will not answer the requirements. At this writing it appears possible that some expedients may be adopted to overcome the instability of this disk; but the probability that it may be made to work satisfactorily is small. In the meantime the makers of such large disks have not succeeded in making one of sufficient uniformity in density. In view of these difficulties the director is disposed to try a thinner disk if one can be found possessing the requisite degree of homogeneity. Thus this project must suffer further delay, although it is practically certain that the difficulties presented may be ultimately overcome.

### *Investigations of Research Associates and Collaborators*

The relations of research associates and collaborators of the institution are so diversified and complex that they are difficult to specify at any given epoch. Individuals who have received direct aid during the year to their investigations through grants are mentioned in the preceding financial section of this report. Those who have received indirect aid through grants made for the publication of their researches are also mentioned in the section just referred to. Many collaborators and assistants have received compensation directly from research associates in charge of investigations, while some research associates and many collaborators have received no direct compensation. It appears to be neither desirable nor practicable at present to seek any higher degree of correlation of this work, since it is carried on by many individuals in many different parts of the world. The best evidences of the quantity and quality of the results accomplished are to be found in the publications listed in part in a subsequent section of this report and more at length in the general bibliography of the year published in the current year book. The work of the year has extended to an aggregate of more than twenty different fields of research and has occupied the attention of more than a hundred investigators. Many of these have rendered special reports to be published in the year book, while reference is made to the work of many others in the reports of the larger departments of research.

### FINANCIAL STATEMENT FOR FISCAL YEAR 1911-12

The sources of funds available for expenditure during the past fiscal year, the allotments for the year, the revertsments made during the year, and the balances

THE ADMINISTRATION OF THE FUR  
SEAL SERVICE

THE report of the House Committee on Expenditures in the Department of Commerce and Labor, on the administration of the fur seal service, has been made public as House Report, No. 1425, 62d Cong., 3d Ses. It contains a majority report, signed by Representatives Rothermel (chairman), McDermott, Young and McGillicuddy; a statement of "views of the minority," and the minority report, signed by Representatives McGuire, Madden and Patton.

This committee, in the course of its investigation, held numerous hearings extending from May 31, 1911, to July 31, 1912. The testimony heard comprises 1,013 pages, with an appendix of correspondence and documents numbering 1,232 pages. The majority report is divided into 7 counts, five of which have to do with certain alleged harmful or unlawful acts of the two leasing companies which we need not now go into. They are ancient history, since the fur seal herd is now, and has been since 1910, in sole charge of the government.

The sixth item in the report deals with the period of government control, and states that "in spite of the express prohibition of the law, it is disclosed in the testimony that yearling and female seals have been killed by the agents of the government in charge of the seal islands." One looks in vain in the testimony for any such evidence. On the other hand, the testimony clearly shows that of the 13,500 skins taken in 1910 (of which 12,920 were sold in London in December of that year), the season under particular consideration, only 90 were under the standard weight of the two-year-old, as shown by the green weights taken by the agents on the islands, and only 92, by the salted weights of the London fur dealers. With these possible exceptions, no yearling animals were killed; and in the period from 1904 to 1911, in which the individual weights of over 90,000 skins were taken, only 700 skins were underweight. These exceptions may represent accidents or mistakes in judgment, it being necessary for the clubber to

judge the weight of the skin while the animal is alive. It was, furthermore, not against the law to kill yearlings; the prohibition in this case was by departmental regulation. The charge that females were killed depended upon the alleged commingling of the sexes in the yearling class. It is not a fact that the yearling males and females commingle on land, but this is not necessary to disprove the charge, as yearlings are shown not to have been killed, except in the few exceptional cases above noted.

The charge of killing yearlings was in itself a most insignificant one. Representative Townsend, whose resolution brought on the investigation, asserted in his opening address that 30,000 such animals had been killed. Mr. Henry W. Elliott, the complaining witness, placed the number at 128,000. The total number of animals killed by the North American Commercial Company during its twenty-year period scarcely exceeded 300,000. It may be noted that other testimony, by Mr. Alfred Fraser, showed that in this very same period more than a million seals had been killed at sea, of which we know from other sources fully 80 per cent. were gravid or nursing females. This fact together with all other facts relating to the effect of pelagic sealing upon the fur seal herd is ignored in the majority report.

Item 7 of the majority statement recites how "the testimony taken before the committee was the basis in large measure of the action of Congress . . . which establishes a closed term of five years . . . to all commercial killing of seals." The testimony nowhere discloses any valid reason for the suspension of commercial sealing. On the contrary, the testimony contains the positive assertions of such authorities as Dr. D. S. Jordan, of Stanford University; Dr. L. Stejneger, of the Smithsonian Institution; Dr. C. H. Merriam, late of the U. S. Biological Survey; Dr. F. A. Lucas, of the American Museum of Natural History; Dr. C. H. Townsend, of the New York Aquarium, and others, all of whom have visited the fur seal islands in recent years and made studies of the animals, to the effect that such suspension is not only not necessary, but

is likely to prove highly detrimental to the welfare of the herd.

The majority report is summed up in a series of recommendations. The first four provide for confiscation of the bond of the North American Commercial Company, for suit for damages against the original president of that company, for rectification of a wrong against Russia in the matter of a seizure of a sealing vessel—all matters foreign to the interests of the herd. The fifth recommendation only is pertinent and this we may give in full. It is as follows:

(5) That in view of the closed season of five years provided by act of Congress, of August 15, 1912, the services of the Treasury agents on the said Pribilof Islands can be dispensed with, resulting thereby in a saving to the Federal Government of approximately \$25,000 annually.

Presumably the act of Congress refers to the Sulzer bill which is actually of the date of August 25. There have been no treasury agents on the Pribilof Islands since 1903, when the islands were transferred to the Department of Commerce and Labor. But these are matters of detail. The important thing is that the government force on the islands is to be disbanded. These men have charge of 300 natives who must be governed, fed and clothed. The law still permits the killing of a few animals for natives' food. Their skins must be cared for. The blue foxes must be cared for and fed. There is a reindeer herd on each island. The rookeries are in need of betterment work, especially in the eradication of areas infested with the hookworm, destructive of the young pups. The recommendation of Mr. Rothermel and his colleagues would abandon the islands and their inhabitants to their own devices for five years. When left without restraint it is well known that the natives are unable to resist the temptation to kill pup seals for food. That they would kill thousands of young seals for that purpose, should the agents be absent, is certain. Are Mr. Rothermel and the three who united with him in this recommendation willing to assume the responsibility for this waste which is quite sure to take place if their advice

be accepted by congress? In return the government would effect a saving of \$54,750. (The salaries total only \$10,950 annually instead of \$25,000 as stated in the Rothermel report.) The suspension of land sealing which has paved the way for this magnificent stroke of economy involves the wasting of at least 63,000 superfluous males which at the age of three years would give skins worth \$40 each, a cash loss of \$2,500,000, to say nothing of the damage these animals will occasion to the mother seals and their helpless young by their fighting.

It is hard to see how this recommendation came to be written. Some explanation is deducible from a significant paragraph in the minority statement which follows:

Although the committee took more than 1,000 pages of testimony, and the last hearing was six months ago, on July 31, 1912, the committee has never held a single meeting for the purpose of considering the evidence, and the report made by the chairman was never submitted to the committee for its consideration; no meeting of the committee was ever held for this purpose, and we are not satisfied that it has been approved by a majority of the committee.

This interesting commentary is followed by further equally interesting comment, and then comes the minority report itself. This is an able document and treats the investigation from the only rational standpoint, the welfare of the herd. The charges are stated in detail. The natural history points necessary to an understanding of the problems are accurately set forth. The methods of land sealing and of pelagic sealing are discussed, with their effect on the herd. The charges are then specifically treated in the light of the testimony and found to be without support. The minority's conclusions are expressed in the following words:

We are convinced that the sole important cause of the decrease of the fur-seal herd during the last decade has been pelagic sealing, and that land killing, as practised on the Pribilof Islands during that time, has had nothing to do with the diminution of the herd.

After a careful examination and consideration of all the evidence, we find that the administration of the fur-seal service by the Department of Com-

merce and Labor and by the Bureau of Fisheries of that department has been in accordance with the law; that the regulations issued from time to time by the department and the instructions issued to the agents have been properly observed; that the fur-seal herd has been handled intelligently; and that the charges have not been sustained.

The charges of malfeasance brought with such a flourish against the Department of Commerce and Labor by Mr. Henry W. Elliott, with the support of Dr. William T. Hornaday and a very small minority of the Camp Fire Club, whom the majority report characterizes as "public spirited citizens," have proved a fiasco. It is said that they influenced the action of congress in suspending land sealing. We can well believe this. The aforesaid congressional action provides for the throwing away of \$2,500,000 worth of seal-skins, jeopardizes the permanence of a beneficent treaty which is essential to the only salvation of the herd, and inflicts upon the rookeries a horde of idle fighting bulls to work destruction among the breeding females and their young. There is a close resemblance between this ill-advised action of congress and the equally unwarranted investigation, as disclosed in the dual report of the committee conducting it.

If congress had wished to enact a law for the encouragement of pelagic sealing it could scarcely have done so more effectively than it did when it prohibited commercial killing on the land of the surplus male seals.

GEORGE ARCHIBALD CLARK

STANFORD UNIVERSITY, CAL.,

February 11, 1913

#### THE ALPINE LABORATORY

THE Alpine Laboratory is situated at 8,500 feet on the Cog Railway between Manitou and the summit of Pikes Peak. The flora is both rich and varied, and in connection with the remarkable diversity of habitat found in this rugged mountain region offers exceptional opportunities for the study of plant response, and the origin of new forms. Among the alpine summits of the continent, Pikes Peak is unique in the series of great formational

zones which lies across its face. From the Great Plains grasslands, the series runs from valley woodland at 5,800 feet to mesa, chaparral, foothill woodland, pine forest, aspen woodland and spruce forest to alpine meadow, rock field and bog at 11,000-14,000 feet in a distance of 7 miles. From the very nature of the mountains, weathering, erosion and other physiographic factors bring about the almost countless repetition of the same or similar habitats, and produce numbers of primary and secondary successions illustrating a wide range of developmental processes and principles.

Ecological work was first done at Pikes Peak in 1899, and has been carried on each summer since that time. In consequence, it is probable that no other area has been so intensively studied by means of instrument and quadrat, and offers such a fascinating array of ecological problems for which the foundation has at least been sketched. The scope and nature of this foundation work is indicated by the following publications: "Development and Structure of Vegetation, 1904"; "Research Methods in Ecology, 1905"; "Relation of Leaf Structure to Physical Factors, 1905"; "Vegetation of the Mesa Region, 1906"; "Life History of the Lodgepole Burn Forests, 1909"; "Natural Vegetation as an Indicator, 1910"; "Wilting Coefficient, 1911," and "Development and Structure of Sandhill Vegetation, 1913."

The practical aspects of quantitative ecology are represented by the Fremont Forest Experiment Station, and the Dry-land Agriculture Field Station of the U. S. Department of Agriculture, perhaps the best equipped stations in the world for the exact study of vegetational problems.

The field of investigation open falls into four general divisions: (1) the use of quantitative methods of studying habitat and plant; (2) the application of ecological methods and principles to forestry, agriculture and plant pathology; (3) the measured study of individual response to the habitat with especial reference to the origin of species; (4) quadrat study of the development and structure of plant formations. The oppor-

tunity for applying the exact methods of modern ecology to the problems of Silvics, Forest Pathology, Dry-land Agriculture, Plant Breeding and Experimental Evolution is unsurpassed. Opportunity will also be offered for the taxonomic study of the varied flora.

While the plan contemplates graduate work primarily, advanced students in botany or related subjects, such as forestry and agronomy, will be accepted, provided they have had sufficient training to enable them to work on individual problems under adequate supervision. It is hoped that the opportunity will be especially welcome to foresters, pathologists, agronomers and teachers of botany who have not yet become acquainted with the methods and outlook of exact ecology, and its many applications to practical plant science. The summer's work will be accepted as the full equivalent of a semester's work for the master's or the doctor's degree at the University of Minnesota, and the University of Nebraska. It is expected that other universities will permit similar arrangements.

FREDERICK E. CLEMENTS

THE UNIVERSITY OF MINNESOTA

#### SCIENTIFIC NOTES AND NEWS

DR. FELIX KLEIN, professor of mathematics at Göttingen, is about to retire from active service.

MRS. A. R. WALLACE writes to an American correspondent: "Dr. Wallace is very well and busy, writing as hard as ever; he has just passed 90, and feels like 50."

DR. JAMES M. TAYLOR will retire from the presidency of Vassar College at the close of the present year.

DR. ALEXIS CARREL, of the Rockefeller Institute for Medical Research, has been appointed a knight of the Legion of Honor by the French government.

DR. F. W. PUTNAM, professor emeritus of anthropology at Harvard University, has been elected non-resident vice-president of the Washington Academy of Sciences.

PROFESSOR S. W. WILLISTON, of the University of Chicago, will attend the ninth Inter-

national Congress of Zoology as the delegate at large of the American Zoological Society.

THE Lalande Prize, of the Paris Academy, has been awarded to Professors H. Kobold and W. Wirtz for their work on the determination of the motions of nebulae.

THE Bessemer gold medal of the Iron and Steel Institute will be awarded to Mr. Adolphe Greiner, general director of the Société Cockerill, Seraing, at the annual meeting to be held in London on May 1 and 2.

At the last meeting of the Royal Australasian Ornithologists' Union of Melbourne, Australia, Dr. R. W. Shufeldt, of Washington, D. C., was elected an honorary member.

Two bronze horses, made by George Ford Morris, the New York animal artist, illustrating the points of an ideal draft horse, and the deficiencies of an inferior horse, have been presented to Dr. A. S. Alexander, of the University of Wisconsin, in recognition of his work in developing the horse breeding industry, both of Wisconsin and the country at large.

DR. EDWARD A. BURT, professor of natural history (botany) in Middlebury College, Middlebury, Vt., has been appointed librarian and mycologist of the Missouri Botanical Garden, St. Louis, Mo. He will leave Middlebury at the close of the present college year and begin his work at the Missouri Botanical Garden in September.

At the recent annual meeting of the board of managers of the Wistar Institute of Anatomy and Biology, Dr. Helen Dean King was elected assistant professor of embryology. Dr. King will continue the embryological work of the institute which was begun two years ago by Professor G. Carl Huber, who has returned to the University of Michigan.

DR. ROBERT H. LOWIE, of the department of anthropology of the American Museum of Natural History, has been promoted to the rank of associate curator.

MR. WILLIAM ROBERT OGILVIE GRANT has been promoted to be assistant keeper of the department of zoology at the Natural History

Museum, South Kensington, in succession to Mr. Edgar Smith, who will retire, by reason of age, on March 31.

DR. WILLIAM MCPHERSON, professor of chemistry and dean of the Graduate School at the Ohio State University, has been granted a leave of absence for the second semester. He will spend the semester in Germany.

DR. BRYANT WALKER, of Detroit, Michigan, will bear the expense of a zoological expedition to Colombia, South America, in the summer of 1913. The field party will consist of the head curator of the museum, Dr. A. G. Ruthven, Professor A. S. Pearse, University of Wisconsin, honorary curator of crustacea, and Mr. Frederick Gaige, of the department of zoology, University of Michigan. The work will be carried on in the Santa Marta Mountains, and will consist principally of detailed studies of the local distribution of the crustaceans, molluscs, ants, amphibians and reptiles, although an attempt will be made to get specimens of other groups needed in the museum.

PROFESSOR HARRIS HAWTHORNE WILDER, of the department of zoology at Smith College, and Mrs. Wilder, instructor in zoology, have been given leave of absence for the second half year, and will proceed to Naples.

PROFESSOR JAMES HAYDEN TUFTS, head of the department of philosophy in the University of Chicago, will be the convocation orator at the eighty-sixth convocation of that institution on March 18, the subject of his address being "The University and the Advance of Justice."

PROFESSOR LUDWIG ASCHOFF will deliver the Cartwright lectures of the Association of the Alumni of the College of Physicians and Surgeons, Columbia University. There will be two lectures, the subjects being "Thrombosis" and "Contracted Kidney," and they will be given at the New York Academy of Medicine on March 12 and March 15.

PROFESSOR LUDWIG SINZHEIMER, of the University of Munich, has arrived in Madison, where he will give a course of lectures in the

University of Wisconsin during the second semester. His subjects are "Industrial Labor Problems" and "Methods of Social Reform."

MR. JOHN M. GOODELL, Assoc.Am.Soc.C.E., consulting engineer, *Engineering Record*, New York City, on February 20 delivered a lecture on "Essentials of Technical Writing," before the graduate students in highway engineering at Columbia University.

By invitation of the scientific faculty, Professor George Grant MacCurdy, of Yale University, gave a public lecture at Dartmouth College on the evening of February 10, his subject being the "Antiquity of Man."

HARLAN I. SMITH, of the Geological Survey of Canada, delivered an illustrated public lecture on January 28 in the Normal School, Ottawa, on "Modern Museum Work for the Scientist, the Teacher and the Public" under the auspices of the Ottawa Field Naturalists' Club.

DR. ROLLIN A. HARRIS, of the U. S. Coast and Geodetic Survey, lectured before the Sigma Xi Society of Cornell University on February 10. His subject was "The Leading Characteristics of the Tides."

WITH the support of the Christiania and Leipzig Academies, the firm of B. G. Teubner contemplates the publication by subscription of the collected works of Sophus Lie, edited by Friedrich Engel.

THE *American Museum Journal* states that by the death of the artist, Louis Akin, at Flagstaff, Arizona, on January 2, the museum's plans for mural decorations for the Southwest Indian hall have received a check. Mr. Akin had been commissioned to prepare tentative sketches for sixteen panels and had made a number of preliminary figure studies with that end in view. He expected to have finished the sketches during the present year. It is hoped that it may be possible to exhibit Mr. Akin's studies during the spring months when there is proposed a special exhibit of material and paintings illustrating the life of the Indians of the Pueblo region. Mr. Akin is best known to the world by his paintings of

Hopi Indians. His work is a faithful portrayal of the tribe, with which he lived during the years of his study and of which he was made a member.

WE learn from *Nature* that the friends of the late Mr. H. O. Jones, F.R.S., who with his wife met his death last summer in the Alps, are of opinion that some permanent memorial to him should be established in the University of Cambridge. There is at present no teaching post especially associated with physical chemistry in the university, and as the laboratory now affords opportunity for study and research in this modern branch of chemistry, the committee appointed for the purpose of the memorial recommends that the endowment of such a post in connection with physical chemistry would form an appropriate and a lasting memorial to Mr. Jones, and one calculated to further a cause in which he was peculiarly interested. Subscriptions to the extent of more than £2,750 have already been received.

DR. SAMUEL ALLEN LATTIMORE, professor of chemistry at the University of Rochester for more than forty years until his retirement as professor emeritus in 1908, died on February 17, aged eighty-four years. Professor Lattimore was a vice-president of the American Association for the Advancement of Science in 1880.

DR. J. E. MANCHESTER, instructor in mathematics at the University of Minnesota, and previously president of Vincennes University, died on January 24, aged fifty-seven years.

G. HAROLD DREW, B.A., of Christ's College, Cambridge, and research associate of the Department of Marine Biology of the Carnegie Institution of Washington, died on January 29.

THERE will be a civil service examination on April 9, for the position of miscellaneous computer in the Naval Observatory.

THERE will be New York state civil service examinations on March 22 for the position of chief medical officer, port of New York, at a salary of \$2,500, and locomotive boiler inspector in the second district, at a salary of \$3,000.

A REPORT has been received at the American Museum of Natural History from the South Georgia Islands expedition under Mr. Robert C. Murphy, which reached the Bay of Islands, November 27, and was waiting for the sea elephant season to open in order to obtain the desired specimens for a museum group of this Antarctic species. Mr. Murphy's statement that there were already on the ground twenty-one steamers representing seven commercial companies, mainly Norwegian, is discouraging for the future of the southern sea elephant race even with the close season set upon the species by the English. The South Georgia Islands expedition, made possible through the liberality of Mr. Arthur Curtiss James, hopes to obtain young penguins needed for completion of a penguin group under construction at the American Museum, in addition to sea elephants and a general collection of birds.

AT the stated meeting of the College of Physicians, Philadelphia, held on February 5, an Assyrian medical tablet, dating from the seventh century B.C., the gift of Drs. S. Weir Mitchell and Richard H. Harte, was presented by Dr. F. P. Henry.

THE mental hygiene exhibit prepared for the International Congress of Hygiene and Demography will be held in Philadelphia, March 13-22. The exhibit consists of charts, statistics, photographs and models showing past and present methods of care for the insane.

THE Stanford University Medical Department announces the thirty-first course of popular medical lectures to be given as follows:

February 7—"Eugenics," President David Starr Jordan.

February 21—"The State and the Physician," Professor J. G. Fitzgerald, University of California.

March 7—"Grafts and Transplantations of Human Tissue," Dr. Leo Eloesser.

March 21—"The Work of the Medical Department of the U. S. Army on the Firing Line"

(illustrated), Captain James L. Bevans, Medical Corps, U. S. Army.

April 4—"Some Skin Diseases We Need not Have" (illustrated), Dr. H. E. Alderson.

April 18—"The Work and the Aims of Our Health Department" (illustrated), Dr. R. G. Brodrick, Health Officer of San Francisco.

THE provision of satisfactory municipal and domestic water supplies constitutes one of the most important problems that is presented to our cities and towns. The municipalities that are situated within easy reach of upland country can as a rule obtain pure water from the uninhabited highland drainage areas. Those located in the flatter portions of the country must depend on the local rivers or on underground sources. With increase in population the rivers inevitably become so polluted that it is necessary to purify the water before it can be devoted to domestic use. Such conditions prevail in the prairie region along the Ohio Valley and especially in the states of Ohio, Indiana and Illinois. Most of the larger cities in this region resort to purification of polluted river water. Cincinnati, Columbus, Indianapolis, Louisville and many smaller cities maintain filtration systems. For small cities and towns it is frequently possible to procure underground water supplies that will be sufficiently constant to warrant development. Some years ago the United States Geological Survey started investigations of ground-water supplies in the Ohio Valley. As a result two reports have already been published. The survey now announces the publication of a third, entitled "The Underground Waters of Southwestern Ohio," by M. L. Fuller, F. G. Clapp and R. B. Dole. The area covered by this report comprises about 5,600 square miles, or about one seventh of the state. The region receives abundant rainfall, but the streams are rather far apart and the springs are few and of small volume. This portion of Ohio is densely populated, the average population being about 150 to the square mile in the area as a whole and 50 in the rural districts, and as it contains many paper mills, distilleries and other manufacturing establishments the river waters are in

many places badly polluted by sewage and industrial wastes, which render them unfit for drinking. For this reason carefully protected ground-water supplies are highly desirable for domestic purposes, especially in the cities and crowded villages, where the nearness of houses, barns and cesspools may make wells unsafe sources of drinking water. In this portion of Ohio immense quantities of water are also required in the industries, and as the waters of the streams are generally too muddy and too uncertain in quantity for this purpose, wells are largely used, and the need of more specific information concerning ground-water supplies is urgent. Limestones predominate in this region, extending in some places to depths of hundreds of feet, and the lack of sandy water-bearing beds makes the ground-water problem especially difficult. Fortunately, however, the surface is covered with a sheet of unconsolidated pebbly clay, underlain locally by some sand and gravel, and nearly all the larger valleys are deeply filled with sand, gravel or unconsolidated glacial material. These deposits contain much underground water, largely of local origin. Many of the wells on low ground, both those in rock and those in the alluvial fillings of the valley, yield flowing water, and nearly everywhere the water is under artesian pressure, rising very materially when encountered. In general, deep wells give no promise in this region, for, though water can be obtained from such wells in most places, it will generally be either salty or highly charged with sulphur.

#### UNIVERSITY AND EDUCATIONAL NEWS

GIFTS aggregating more than \$1,000,000 to Washington and Lee University, Lexington, Va., are provided for in the will of Robert P. Doremus, member of a New York Stock Exchange firm, who died on February 1 last. Mr. Doremus was a graduate of Washington and Lee University.

AN increase of \$12,800 in the annual state appropriation for Middlebury College has been made by the legislature of Vermont.

MISS EMILY SOUTHMAYD, of New York City, has presented Yale University with \$125,000 to found a chair of equity jurisprudence in the Yale Law School in memory of her brother, the late Charles F. Southmayd.

THE American Telegraph and Telephone Company has given the Massachusetts Institute of Technology \$5,000 a year for five years to catalogue and maintain the electrical library recently given to the institution. It is also reported that the American Telegraph and Telephone Company will support research work in electricity at the institute.

MR. G. A. WILLS and Mr. H. H. Wills have given £150,000 for the extension of the buildings of Bristol University, in memory of their father, who was the first chancellor. Their brother, Mr. W. M. Wills, has offered £20,000 for the general endowment fund of the university.

In the *President's Report*, issued this month by the University of Chicago Press, President Harry Pratt Judson says: "It is of course well understood as a distinct policy of some educational institutions to spend what is necessary regardless of resources, depending upon alumni and friends of the institution to provide the resulting deficit. It is not the belief of the University of Chicago that deficit financing is safe from any point of view." The report shows that there was a surplus for last year of \$17,270.29. It also shows that about forty-three per cent. of the total income of the university for the year was derived from students, that the sum of \$107,441.14 was returned to them in the form of fellowships and scholarships, and that fifty-six per cent. of the total expenditures was paid for instruction. During the year the sum of \$1,087,178.92 was paid in in the form of gifts. The total gifts paid in from the founding of the university to June 30, 1912, amounts to \$33,784,523.81.

At Yale University Dr. William Ernest Hocking has been promoted to be professor of philosophy, and Dr. Frederick Rogers Fairchild to be professor of political economy.

## DISCUSSION AND CORRESPONDENCE

### THE MEMORIAL TO ANTON DOHRN

IN the issue of *SCIENCE* for November 10, 1911, was printed a statement concerning the memorial to Anton Dohrn, with an appeal from the executive committee of the American subcommittee for subscriptions to a fund to be established for this purpose. The subscription is to be closed May 1, 1913, and it is hoped that additional contributions may be received before that date. The American subscription is still far short of what the committee had hoped for, and should be increased if this country is to be creditably represented in the general fund. Checks should be drawn to the order of the Anton Dohrn Memorial and sent to Mr. Isaac N. Seligman, care of J. and W. Seligman and Co., No. 1 William St., New York City.

EDMUND B. WILSON,  
*Chairman of the American Subcommittee*

COLUMBIA UNIVERSITY,  
NEW YORK, N. Y.

### A SUGGESTED FORMULA FOR BIOLOGISTS

It is a well known fact of observation that the smaller creatures are ever the more vigorous. A flea is proportionately vastly more powerful than a cat; and the cat than an elephant. While in paleontology giantism is, I think, recognized as a stigma of degeneracy, preceding racial extinction.

Now, may not these observations be embodied in the following single mathematical form.

The weight of any two similar animals is plainly proportionate to the *cube* of their heights. While their muscular power may surely be taken as proportionate to the area of the similar cross sections of corresponding muscles; and thus proportionate to the *square* of their heights. So that, of 2 cats say, if *B* be *n* times higher than *A*, then it is *n*<sup>3</sup> times heavier; but has only *n*<sup>2</sup> times more muscular strength. And is thus really 1/*n* proportionally weaker. For, plainly, during any corresponding exertion, it must move *n*<sup>3</sup> more weight, with but *n*<sup>2</sup> more strength.

ALAN S. HAWKESWORTH

## SCIENTIFIC BOOKS

*The Mechanistic Conception of Life.* By Professor JACQUES LOEB. University of Chicago Press. 1912. Pp. 232.

The title and the contents of this volume convey very different impressions to the reader. The title leads one to expect that in the volume one will find a demonstration that vital phenomena are mechanistic, or an exposition of the organism as a mechanism, or some discussion of the points at issue between the mechanist in biology and his opponent, the vitalist. But, on reading the book, this expectation is not realized. Instead one finds, as the preface states, that the volume consists only of "essays—written on different occasions mostly in response to requests for a popular presentation of the results of the author's investigations." Indeed, it is further quite frankly acknowledged, that "the title of the volume characterizes the general tendency of these investigations as an attempt to analyze life from a purely physical-chemical viewpoint." The papers which make up the volume deal primarily and almost exclusively with the following subjects: The Activation of the Egg and Heredity, Tropisms, the Comparative Physiology of the Nervous System, Pattern Adaptation in Fishes, Physiological Morphology, Fertilization, Artificial Parthenogenesis, The Prevention of the Death of the Egg, and the Experimental Study of the Influence of the Environment on Animals.

Of the actual contents so far as they correspond to what is indicated by the statements of the preface a reviewer need make no criticism. Suffice it to say in description of them, that they consist for the most part of the narration and interpretation of various experiments in application of physical chemistry to certain isolated cases of vital phenomena. In the employment of this method Professor Loeb has been, as is well known, a pioneer, and no one can gainsay the importance of his discoveries. They form one of the most dramatic chapters in the history of biology. Indeed one can but recognize the brilliancy of Professor Loeb's hypotheses and

experiments in attacking specific problems, and be grateful for the stimulus which his viewpoint and resulting methods have given to biological research. In general, one can only praise *any* new experimental method which brings results, and one can not repudiate by mere argumentation the facts which such a method reveals. Thus it would be only by repeating Professor Loeb's experiments and finding that they do not give the results which are claimed for them, or by throwing doubt upon them by cognate experiments, that one could put himself in a position justifiably to dispute or criticize the experimental data which are presented in the volume under review. Accordingly, since the greater part of Professor Loeb's book deals with specific methods and results of the kind just indicated, it is left for a reviewer to make only a few comments and general criticisms. However, by way of fulfilling this function, it would seem pertinent to raise the question, especially *à propos* of the title of the book, why Professor Loeb should have selected these particular essays to place under the caption of *The Mechanistic Conception of Life*, when he has so many others that would have served the purpose equally well. Further, it may be remarked concerning the papers selected and now called "Essays," that there is not discoverable, either in their arrangement or in the data which they present, any system which converges to that which both the title and certain emphasized statements of the volume would indicate to be its chief purpose and claim, namely, the demonstration of the applicability, in some specific sense, of the mechanistic conception to *all life and to all that life manifests*. One can make this criticism, and yet admire the brilliancy and fruitfulness of Professor Loeb's experiments. One can indeed thus criticize, and yet be convinced that in *some sense* the mechanistic conception of life is the correct one, and certainly that it is a very fruitful one in stimulating such experiments as Professor Loeb's. But one can hold this conviction, and still find good reasons for maintaining that *such* experiments, consisting for the most part of the application

of physical chemistry to a relatively few vital phenomena, do not prove that *life and all its manifestations* are mechanistic in any but the most general sense of this term, if, indeed, in this way. While a reviewer, then, may not, perhaps, be in a position to take issue with Professor Loeb's specific experiments and results, he may be permitted to make a few comments concerning the method which conceivably might lead to the establishment of Professor Loeb's broad generalizations, or, at least, would clarify them.

It would certainly seem, if one wished to demonstrate that life is, or is not, mechanistic in any exact sense, that one should, for example, state with precision that meaning of this term which is commonly accepted by authorities on mechanics. The term thus defined is, that mechanics is the science of masses moving, and acted upon by forces, in accordance with Newton's laws and the principles of d'Alembert, of Hamilton and of Lagrange. Having thus defined the term either in this or in some other precise way, one could then ascertain whether the organism has such characteristics as warrant putting it in its entirety, or in part, under the conception of mechanism. But Professor Loeb nowhere pursues this method. For his broad generalization, his only real argument, stripped of its rhetorical clothing, is, that, since certain relatively isolated life phenomena can be experimented with by the methods of chemistry, physics and physical chemistry, and accounted for by the results of these sciences, *all life in all of its aspects* is mechanistic. However, it is clear that this conclusion in any precise sense follows, provided only that chemical, physical and chemical-physical phenomena are themselves mechanistic in some precise and technical sense of the term. But, whether they are this or not, and, if they are, to what extent, are themselves questions which are to-day undecided, or, at least, usually not made clear. Vital phenomena do undoubtedly involve chemical and physical processes, but these processes at the present time have themselves not been successfully treated by all the orthodox mech-

anistic principles. At best one finds physico-chemical phenomena treated only from the standpoint of the law of the conservation of energy and the second law of thermodynamics. However, the criticism which on this ground can be made against Professor Loeb is one that is by no means to be directed against him alone, but can be made a very general one. For the only argument that is usually found among biologists for the mechanistic conception is the one which he presents. In fact, with this the case, it must be said, that really all that most biologists mean by "mechanistic" is what Professor Loeb means, namely, that which is physical, chemical and physical-chemical, or, more precisely, simply that which is *determined or caused*. However, *there is a more exact scientific meaning of the term* in accordance with which it may fairly be asked, if physical and chemical phenomena are *ever wholly and exclusively* mechanistic. Put with precision, the question is, whether these phenomena are wholly and exclusively moving masses acted on by forces, as defined, described and explained by Newton's laws and the classical principles previously mentioned. Thus stated, the question suggests the broader and more important ones, scientifically and philosophically: Are *all* the things with which we are acquainted in this universe of ours mechanistic in this precise sense, and, if they are, what does this mean? Does it mean that *all* phenomena are *reducible* to masses in motion in the sense that they ultimately consist of nothing but these moving masses, or does it mean only that *all* phenomena are *compatible* with the laws of moving masses acted on by forces, but are nevertheless more than motion and masses, even as, for example, physical objects are numerical, but are more than the positive integers with which they are in one-one correspondence? These two concepts, "reducible to" and "compatible with," are radically different in their implications, and it is difficult to find either the biologist or the physicist who, holding to the universal applicability of the mechanistic conception, makes them clear. However, if one contends that something, say, the organism, is mech-

anistic, and interprets this to mean either "compatible with" (Loeb) or "reducible to" mechanism, then, in order merely to comply with the usual principles of *scientific* procedure, should he not determine with at least some precision the meaning of these terms? Otherwise, does not the claim, that the object under examination is mechanistic, have only the most general and indefinite meaning, such as "determined," etc.? Indeed, is not this meaning the only one that characterizes the position of most biologists, that life and life's phenomena are mechanistic? But is not "determined" itself a very general and indefinite concept, awaiting, for precision, the specification of particular causes?

As concerns method, then, the reviewer is of the opinion that neither the experiments described by Professor Loeb in this volume, nor, in fact, the whole list of results and experiments obtained up to the present time in application of physical chemistry to vital phenomena, scientifically justify the sweeping conclusion, either insinuated or made explicit, that life and all that life manifests in the field of conduct (ethics), science, religion and art, etc., are mechanistic in any precise sense. Such phenomena may be determined and caused. That few would deny. And they *may* also be mechanistic in some more precise and technical sense of the term. But until that sense is defined, and the meanings of such terms as "reducible to," "compatible with," and "explainable by" are specified with precision, so that it can be ascertained whether or not life and life's manifestations are of such specific character as in some one of these ways to be brought under mechanism, proof is lacking for what is otherwise only a vague conviction. However, in the present stage of the analysis of most phenomena manifested by living beings, both human and non-human, there does not seem to be discoverable sufficient evidence to show that they are reducible to, or explainable by mechanistic principles in any other than the most general sense. The successful application of physical chemistry to certain isolated biological phenomena must, of course, be admitted, and the

position that all of life's manifestations may ultimately be also so *related* must be regarded as a perfectly permissible working hypothesis. But at the present time the position that mechanics, physics and chemistry are, or ever will be capable of *explaining*, in any precise sense, the greater part of vital phenomena and of life's manifestation, is so remote from the experimental facts, that it can be regarded as only a pure assumption.

The reviewer can find, then, only a minimum either of justification or of meaning in such claims as Professor Loeb's book purports to make, namely, that *all* human conduct, in morals, esthetics, scientific thinking and religion, is mechanistic. Nor is there any more justification or meaning for the view that it is provided only all such phenomena are mechanistic and can be related to physical chemistry, that there can be a science of them. One might as well claim that, until the brain is completely explained by physical chemistry, there can be no science of mathematics, since the mathematician's thinking is dependent upon his brain. Science is certainly not limited to physics and chemistry and their hybrid, physical chemistry; even where these sciences are not applicable, there may be description and explanation, hypothesis and confirmation, prediction and control, exactness and computation, causation and system.

But further, it may be asked, not as concerns Professor Loeb's methods, but as concerns his broad generalizations, What would they mean even if they were true? What, for example, does it mean to say that ethics, mathematics, literature, law, etc., are mechanistic? Does it mean anything more than that they are *consistent* with mechanistic principles in the technical sense or that the phenomena dealt with in these fields of knowledge are subject to the law of causation? But even with this meaning, would so saying help to understand, or to get at specific results in, the levels of phenomena with which these branches of knowledge are concerned? Would not these branches still continue to exist? And would not the phenomena with which they deal have to be scientifically investigated

at the higher level in order to find something subsequently to be reduced to, or explained by, mechanistic principles if possible? But with *everything* mechanistic in the sense only of being consistent with mechanistic principles, or of being caused, would there not still be something left over which would not be *identical* with mechanism in the precise and technical sense of that term? It is the conviction that there would be—a conviction which can be based on proof—that has actuated the reviewer to write this rather long notice of Professor Loeb's book. Everything that exists is not identical with nor explainable by mechanism in the technical meaning of the term, although it is compatible with it in the sense that one fact can not contradict or exclude the reality of another, and is in some relation with it. And all science is not physics, chemistry and physical chemistry. The tendency of many scientists to maintain the negative of these two propositions is a misleading influence and a stimulus to false hopes, especially when prominence in science lends its weight to the claim. But the tendency is not only a dangerous one; it also represents a bias which is contrary to that broad-mindedness which is held to mark the scientific mind. It is because Professor Loeb's book exemplifies this tendency to so marked a degree, that the opportunity of reviewing the book has been used to enter protest. As a collection of essays in the application of physical chemistry to biology one can only praise the volume. But as a philosophic work, which finds in this application ground for insinuating the universal validity of the mechanistic conception in some precise sense, but really making this only most general, one can only doubt and question. The scientist may justifiably resent the intrusion of the philosopher into science's realm, unless the philosopher becomes scientist. But when the scientist becomes philosopher, as does Professor Loeb, he exposes himself to that broader scientific criticism which is philosophy. The venture may be daring, but does not the daring only seem? For are not "we ourselves only chemical mechanisms"? Then where lieth the blame if some

atoms become philosophers and in the combat some philosophers become atoms?

E. G. SPAULDING

PRINCETON UNIVERSITY

*The Birds of Africa.* By G. E. SHELLEY. Volume V., Part 2. Completed and edited by W. L. SCLATER. London: Henry Sotheran & Co. 1912. Pp. viii + 165-502; pls. L.-LVII.

The publication of Captain G. E. Shelley's elaborate work on the birds of Africa was interrupted in 1906, after the appearance of the first part of the fifth volume, by the serious illness and consequent death of the author. Mr. W. L. Sclater, whose knowledge of the African avifauna well fits him to carry out the original plan, has undertaken to complete the work; and the present instalment is the first to appear under his supervision.

The general treatment of the subject is the same as in previous volumes. Brief diagnoses of superfamily groups, or "sections," are given; also keys to families and subfamilies; with diagnoses of families and keys to genera. Each genus is defined, furnished with proper synonymy, a key to its species, and in most cases with a statement of its geographical range. Under specific headings are given pertinent synonymy; descriptions of the adult plumage of both sexes, and, where possible, of juvenal and nestling; brief measurements, apparently of single birds; a general statement of geographical distribution, and a good account of habits, often two or three pages long, and including mention of many particular localities where the bird has been observed.

Little account is taken of subspecies, when recognized as such, and none are given separate headings. They are treated, if at all, in the text under their respective species, with sometimes a binomial, sometimes a trinomial name. Some are, however, considered as absolute synonyms; while a few are given full specific rank. Of those recognized as subspecies the synonymy is given, and usually, though not always, the diagnostic characters.

The book includes nominally 209 species

belonging to the following five families: Dicruride, Vangide, Campopogonide [lege Campephagide], Laniide and Prionopide. The peculiar genus *Aerocharis* is here in the Vangide, but should constitute a family by itself—Aerocharide.

The genus *Edolius* is synonymized with *Dicrurus*, and *Abbotornis* with *Artamia*; while the several subdivisions of *Lanius* (*Fiscus*, *Enneoctonus*, *Phoneus* and *Otomela*), which have not even consistent color characters for their separation, are all given full generic rank. The generic name *Telophorus* Swainson is very properly given a place instead of *Pelicius* Boie; but no satisfactory generic characters for the group so designated are given to separate it from *Chlorophoneus*, or either of these from *Laniarius*. The name *Tschagra* Lesson is used for the group commonly known as *Telephorus* Swainson, but this should be called *Pomatorhynchus* Boie, as contended by Dr. Reichenow.

Only a single species—*Vanga griseipectus*, from southern Madagascar—is described as new. Our author considers *Laniarius abboti* inseparable from *Laniarius nigrifrons*, but it seems to us to be distinct. Likewise all the readily recognizable subspecies of *Dicrurus adsimilis* (here called by the preoccupied name *Dicrurus afer*) are ignored.

On the eight colored plates fourteen species, including the one here first described, are figured. These plates are by Mr. H. Grönvold, and remind us not a little of the work of the late Mr. J. G. Keulemans.

HARRY C. OBERHOLSER

#### BOTANICAL NOTES

##### ANOTHER AFRICAN PLANT ENUMERATION

A SHORT time ago the writer reviewed Muschler's "Flora of Egypt";<sup>1</sup> and referred particularly to the absence of certain plants, or types of vegetation from the region included in that work (the lower Nile Valley, southward to Nubia), and now we have a contribution from South Africa which permits of some striking contrasts. This second publication is a "First Check-List of the

Flowering Plants and Ferns of the Transvaal and Swaziland," by Professor Joseph Burt-Davy and Mrs. Reno Pott-Leendertz,<sup>2</sup> constituting a 66-page octavo pamphlet, in contrast with the two volumes by Muschler. Yet in this little pamphlet we find enumerated 3,264 species, against 1,632 in the larger work. Moreover, the geographical area covered by the South African pamphlet (117,000 square miles) is less than half that covered by the Egyptian book.

Running rapidly through the check-list, the following numerical data attract attention. There are here recorded 97 species of ferns, including one *Marattia*, 5 Hymenophyllaceae and 78 Polypodiaceae. One finds also of *Equisetum* 1, *Lycopodium* 6 and *Selaginella* 5 species. The conifers are represented by *Podocarpus* (3 species) and *Widdringtonia* (1 species).

Of the grasses there are 146 native and 44 introduced species, the former including such genera as *Andropogon* (11 species), *Panicum* (19), *Eragrostis* (25), while of the sedges there are given 105 species (*Cyperus*, 27; *Scirpus*, 12; *Carex*, 10). Four palms are listed, and 189 Liliaceae (but no *Lilium*), with such genera as *Anthericum* (31 species), *Aloe* (17), *Scilla* (22) and *Asparagus* (13). Iridaceae with 79 species is notable for its 28 species of *Gladiolus*. So too we may note the 123 species of Orchidaceae (*Habenaria*, 23 species; *Disa*, 18 species; *Eulophia*, 31 species).

To give an opportunity for comparison we may mention further that there are 275 species of Leguminosae (*Acacia*, 33; *Crotalaria*, 12; *Indigofera*, 29) and 52 species of Euphorbiaceae. Anacardiaceae include 43 species (*Rhus*, 36); Tiliaceae, 25 species (but no *Tilia*); Violaceae, 2 species (*Viola*, 1); Ericaceae, 11 species (*Erica*, 10); Asclepiadaceae, 156 species (*Asclepias*, 28); Convolvulaceae, 62 species (*Convolvulus*, 14; *Ipomoea*, 37); Labiatae, 103; Scrophulariaceae, 138; Acanthaceae, 108; Cucurbitaceae, 230. Of Compositae there are 304 species (*Vernonia*, 14;

<sup>1</sup> SCIENCE, December 20, 1912.

<sup>2</sup> *Annals Transvaal Museum*, 1912.

*Helichrysum*, 59; *Senecio*, 36; *Aster*, 3; with no *Solidago*, and no *Helianthus*).

Of trees there are many species, but nearly all belong to genera unfamiliar to northern readers. Thus while there are two willows (*Salix*), one *Celtis* and 13 species of *Ficus*, there is no *Pinus*, *Picea*, *Abies*, *Ulmus*, *Frazinus*, *Acer*, *Juglans*, *Quercus*, *Fagus*, *Castanea*, *Betula* or *Alnus*.

The authors are to be congratulated upon having brought out so creditable a list of the plants of their country, and we may express the hope of the botanists of the northern hemisphere that they will be encouraged to follow it soon with a descriptive manual.

#### GREENE'S "CAROLUS LINNAEUS"

At the Linnaean bicentenary memorial exercises held in Washington Dr. Edward Lee Greene gave a notable address (now issued in a little book of 91 pages by the Cower Company of Philadelphia) in which he discussed with rare perspicacity and scientific sympathy the life of "the matchless Swede," Linnaeus. In it he discussed the lineage and childhood of Linnaeus, his school, college and university years; his journey to Lapland; journey to Germany and Holland; his practise of medicine in Stockholm; appointment to be a professor at Upsala, and his influence upon botany. Under the last head Dr. Greene says:

It will be difficult to bring the average botanist of to-day to a realization of how great an epoch in botany Linnaeus created when he began examining the stamens of every plant, with the purpose of ascertaining into what one of his twenty-four proposed classes of flowering plants each generic type must fall. And though it be true that the classes and orders of Linnaeus fell into disuse three quarters of a century ago, it is true to-day that every botanist, from the mere beginner in taxonomy to the most accomplished master of it, if he have a new and unknown plant in hand for determination, makes his final appeal to stamens and pistils. . . . In this procedure every botanist who lives is distinctly a disciple of Linnaeus.

The last chapter of the little book, on Linnaeus as an evolutionist, was prepared two years later (1909) and brings out the fact

that the great botanist was by no means the believer in the "fixity of species" that we have been led to believe. After quoting from the "Philosophia Botanica" which "excludes every idea of a possibly evolutionary origin for any species of plant," Dr. Greene says: "And yet, Linnaeus was an evolutionist," and proceeds to quote later statements which indicate that as the years went on he came to the view that some species may have been derived from preceding species.

The book should be in the hands of every teacher of botany, and we may add zoology, also, since there is a short but very suggestive chapter by Dr. Wm. H. Dall on Linnaeus as a zoologist.

##### MAGMATIC DIFFERENTIATION AT SILVERBELL, ARIZ.

In the course of a study of the ore-deposits of Silverbell, Pima County, Ariz., some interesting facts bearing upon magmatic differentiation were noted. A detailed description of this district has been published,<sup>1</sup> but as that paper is largely devoted to problems in economic geology, it seems advisable to summarize here the facts of interest to petrologists. The region described consists of a complex of late Mesozoic or early Tertiary intrusives entirely surrounding detached blocks of highly metamorphosed limestone. The igneous rocks in the order of intrusion are (1) alaskite, (2) alaskite porphyry, (3) granite, and biotite granite porphyry, and (4) quartz porphyry (dacite porphyry?). Many complex flows of basic composition are found just outside the area studied. The chief problem is the origin of the biotite granite, which is believed to represent a differentiation product of the magma from which the alaskites came.

The alaskite is a light gray rock, consisting almost entirely of quartz and orthoclase, the grains averaging about a half a centimeter in diameter. It contains a little plagioclase, and very rarely shows biotite or hornblende. It is bounded on one side by the later intrusion of

<sup>1</sup> *Bull. Amer. Inst. Min. Eng.*, May, 1912, pp. 455-507.

alaskite porphyry, but in all other directions it disappears under the detrital plains of the desert. The area exposed—about ten square miles—probably represents only a remnant of a more extensive intrusion. The alaskite porphyry, the intrusion next in age, is a rock with a fine felsitic ground mass, carrying phenocrysts of quartz and orthoclase seldom over a millimeter in diameter. It resembles the alaskite in composition, though showing more variation in kind of feldspar. An intrusive contact between the porphyry and the coarse alaskite was found, but the other limits of the porphyry do not fall within the region studied. It was examined over an area of about three square miles. The biotite granite is a holocrystalline rock with an average grain of a quarter of an inch. It is composed of orthoclase, a little plagioclase, quartz and biotite, this last mineral sometimes forming phenocrysts. The relation of this granite to the other rocks is the most interesting petrologic feature of the district. It is found only in the alaskite porphyry, and occurs in three forms: (1) As irregular stocks about fifteen hundred feet in diameter, (2) as small bunches or lenses sometimes only a few feet in dimension, and (3) as well-defined dikes fifteen to twenty feet wide along the contact of the alaskite porphyry and the limestone blocks. In the first two cases the texture is holocrystalline and strikingly coarse even at the contacts. In the third case the rock is a granite porphyry—phenocrysts of quartz, feldspar and biotite in a glassy ground mass.

The fourth rock is more basic than the others, and may be a dacite porphyry, but the large amount of irresolvable ground mass makes its classification uncertain without chemical analyses.

The explanation offered for the above facts is as follows: The original rock magma was an acidic granite, which split into two parts, one rich in biotite, the other practically mica-free. The more acidic portion was intruded first, forming the alaskite and the alaskite porphyry. When the latter rock was only partly cooled, the biotite-bearing portion was intruded, working its way into the still pasty

alaskite porphyry to form lenses, tongues and other irregularly defined masses. Along the borders of the alaskite porphyry cooling had gone further, clean fissures had been formed, and in such places well-defined dikes of granite porphyry resulted. This explains the intimate relationship between the granite and the alaskite porphyry, its various irregular shapes, and the coarse texture in some instances and the fine texture in others. There is a possibility that the quartz porphyry, which contains much biotite, is a still later intrusion of the biotitic phase of the same magma, but distinct evidence on this point is lacking. The relation between the quartz porphyry and the alaskites is not as close as between the granite and the alaskites. The quartz porphyry seems to belong to a distinctly later period of intrusion, while the granites and alaskites are of very nearly the same age.

Although aware of the objections urged against similar hypotheses, I am inclined to attribute the splitting of the magma into two portions to fractional crystallization and the sinking of the heavier biotite crystals. Whether or not this last point is well taken can not affect the conclusion that the granite is a later differentiation phase of the magma from which the alaskites came.

The origin of the granite has important bearing upon the genesis of the ore-deposits. These ores are contact metamorphic copper deposits in the limestones at the contact with alaskite porphyry. They are attributed to magmatic waters given off by the intrusive, in accord with the conclusions reached in similar districts by Kemp, Lindgren and others. But it is noteworthy that the richest ore is found in the neighborhood of masses of granite. Now if this granite is the final product of differentiation of the alaskite magma, it is very probable that it would bring with it increased quantities of magmatic water. The granite and the granite porphyry then partake somewhat of the nature of a pegmatite in that they represent final products of local magma splitting; they differ from pegmatites in texture, and from contemporaneous veins in general in their greater extent. The above facts

show a variation from the general law of decreasing basicity for plutonic intrusions, but this may be explained by the localized character of the phenomena.

FERTILIZATION AND EGG-LAYING IN MICROCOTYLE  
STENOTOMI

ALTHOUGH the process of fertilization of the ovum is readily visible in those animals in which these elements meet outside the body in water, the actual behavior of the internal organs in those other animals where the process occurs within the body is seldom seen. It is for that reason that it seems desirable to describe it as studied in the transparent *Microcotyle Stenotomi*.

Copulation has been carefully observed and graphically described by Zeller in the case of *Polystomum integerrimum*, where the two vaginal orifices are at the lateral margins, but no other description has been found in the literature on the monogenetic trematodes, and in the case of the microcotylinae is of special interest, since although hermaphrodites they can hardly carry out mutual copulation at the same time, as the vaginal orifice is median and dorsal while the penis is protruded from the ventral side.

*Microcotyle Stenotomi*, which occurs on the gills of *Stenotomus Chrysops*, is small enough (2.5 mm.) to become quite transparent when slightly compressed by the coverslip. If a number of these worms be placed alive in a watchglass full of sea water some of them will be seen to go into conjugation after certain repeated preliminary touching together of the anterior ends of the two bodies has taken place. In this passing of the anterior part of the body of one over that of the other the greatest acuteness of sensation is shown. However, after a certain amount of friction together, one worm almost spasmodically becomes fastened by its anterior ventral end, where the genital pore is situated, to the corresponding portion of the dorsal surface of the other in the position of the vaginal opening. They are therefore clasped together by

the anterior ends, almost at right angles to one another, while still supporting themselves on their footlike sucker discs. Because the cirrus and surrounding genital aperture are generally provided with clusters of small hooks the pair is enabled to keep their position during the act.

The spermatozoa pass through the Y-shaped reservoir of the vitellaria to be stored in the seminal reservoir or spermatheca, whence it is ejected as required. A similar provision exists, as is well known, in many animals of more complete development.

In order to follow the later stages in the process of fertilization the worm must be put in a drop of sea water under the coverslip with a hair beside it to prevent too great crushing by the weight of the coverglass, and to allow of the normal movements of the genitalia. Anteriorly and ventrally is the genital pore through which the uterus opens. On the dorsal surface somewhat behind this is the orifice of the vagina. The ovary is a convoluted tube filled with ova which runs across the middle of the body, turning backward to end in an oviduct, while on each side of the body, occupying most of its cavity, is the vitellarium, giving off ducts which unite in a Y-shaped reservoir in the midline behind the ovary. Testes are present in a great group in the midpart of the body toward the caudal end.

In the ovary the ova are immature at the end of the organ, which is turned to the right; toward the other end, as the oviduct is approached, they become larger and mature. The oviduct may be seen proceeding toward the tip of the Y-shaped vitelline reservoir. Before reaching this it is joined by the duct of a small muscular sac which in this case is kidney-shaped and which is the seminal reservoir. If one is fortunate enough to see an ovum leave the ovary on its way toward the uterus, one can also observe that the seminal reservoir contracts spasmodically and injects a fine jet of opaline fluid into the oviduct toward the oncoming ovum, which on meeting the spermatozoa quickens its motion. It recedes a little, then advances again four or five

times as though to come thoroughly into contact with the seminal fluid. Then it passes quietly along the common duct until that is joined by the Y-shaped duct from which the granular yellowish fluid from the vitellaria is churned, as it were, into the oviduct and comes into contact with the ovum surrounding and adhering to it. Continuing on its course the ovum passes into the wider ootype. Here by a vermicular moulding process the yolk is arranged round the ovum and the form of the egg begins to appear. From the ootype, when properly shaped, it passes along to the muscular portion of the uterine canal, which receives the openings of the shell gland. In *Microcotyle Stenotomi* the shell gland appears to be formed of a single mass of cells, the duct from which opens by a wide mouth into the uterus at this point. Generally, however, it is arranged as a mantle of cells about the first portion of the uterus opening by numerous perforations from which exude a chitinous fluid which becomes evenly smeared over the surface of the egg and forms the shell. The egg is now completed with the exception of the long chitinous filaments which are formed by the contractions of the uterus on the soft material. The completed egg passes along into the more distal part of the uterus, where it remains until the worm is ready to deposit it. For this purpose it proceeds to prepare by seizing with its anterior or oral suckers a piece of the gills, but in the case observed under the microscope a bit of waste material was fastened upon because it was convenient. The caudal disc of suckers was also fastened to some support, so that the body was slightly extended. Then a waving motion began, the waves traveling toward the anterior part from the caudal end of the body. After this had lasted for a few seconds the worm began to lash itself up and down, still retaining its hold on the debris to assist its muscular exertions. After the first lashing effort a portion of the anterior coiled filament appeared at the genital aperture; after a short rest a further violent expulsive effort occurred and the pointed end of the egg appeared externally. This was followed by another rest and then

a still more violent expulsive effort which shot the egg against the waste material, where it remained fastened. The whole process was repeated after another short rest, until five eggs were laid, when a long rest ensued and the observation ended.

The process of laying the eggs occupied, all told, probably not more than a minute, but it was striking to see the display of some sort of intelligence by the worm in preparing for the expulsive efforts by seizing the waste material as a fixed point from which to pull.

Although this process of conjugation, fertilization and egg-laying could be directly observed only in this transparent form, it seems entirely probable that it is the same in all the microcotylidæ.<sup>1</sup>

#### ANTHROPOLOGY AT THE CLEVELAND MEETING

THE annual meeting of the American Anthropological Association was held at the Case School of Applied Science, Cleveland, Ohio, December 30, 1912, to January 2, 1913, in affiliation with Section H of the American Association for the Advancement of Science and the American Folk-Lore Society. In the absence of President Fewkes, Drs. Dorsey, Wissler and MacCurdy each presided at the various sessions. President Lomax, of the Folk-Lore Society was also absent, his place being taken by Dr. Charles Peabody, who read the presidential address.

#### SECTION H

Members of the sectional committee present: G. T. Ladd, E. L. Thorndike, W. V. Bingham, G. G. MacCurdy.

Officers for the Cleveland meeting were named as follows: member of the council, Dr. Clark Wissler; member of the general committee, Dr. Charles Peabody. Sectional offices were filled by the nomination and election by the general committee of Professor W. B. Pillsbury, University of Michigan, as vice-president for the ensuing year; Professor George Grant MacCurdy, Yale

<sup>1</sup> The above observations were made at the Laboratory of the U. S. Fish Commission at Woods Hole, Mass.

University, secretary to serve five years; and Professor R. S. Woodworth, Columbia University, member of the sectional committee to serve five years.

The question of a change of name from Section H, Anthropology and Psychology, to read "Section H, Anthropology," raised at the Washington meeting came up for discussion, and the sectional committee recommended that the name remain unchanged for the present.

#### ADDRESSES AND PAPERS

The address of the retiring vice-president of Section H, Professor George Trumbull Ladd, on "The Study of Man," is printed in this issue of SCIENCE. In the absence of President John A. Lomax, of the American Folk-Lore Society, his address on "Stories of an African Prince" was read by Dr. Charles Peabody. Some of the important papers read at the joint meeting are represented in this report by abstracts:

#### *The Ceremonial Schemes of Certain Plains Indian Tribes:* CLARK WISSLER.

Anthropology being essentially a science of culture, one of its necessary concerns is the distribution of cultural traits. In the distribution of such traits we have a complex problem, one of the first steps in whose solution is the description of each culture as found. The next and most interesting step is a comparative examination of these cultures. Were cultural traits all objective, this would be fairly simple, as is the case in many aspects of material culture; but many important traits are not very objective, especially those of a religious, ethical and social nature. When we come to compare religious conceptions of certain Plains tribes, we find a peculiar difficulty. First we are struck by the apparent absolute differences and the absence of all exact parallels. On closer inspection, however, we do find many units or subordinate traits that are exact parallels. It became necessary therefore to develop methods of handling this comparative problem.

It was noted that some tribes seem to have definite ceremonial schemes. The particular schemes for the Dakota, Blackfoot and Menominee were outlined and characterized as general patterns according to which almost every ceremonial was fashioned. The inference here is that if a tribe should take over a new ceremony the tendency would be to work it over into the tribal pattern. Examples of such making over of borrowed ceremonies were cited. The suggestion then is

that in the comparative study of these tribal ceremonies allowance must be made for the deliberate change of pattern and evidences of contact sought in parallel units of a more detailed character.

#### *Notes on Eastern Sioux Dances:* ROBERT H. LOWIE.

The Santee, Wahpeton and Sisseton, though differing somewhat among themselves, shared a number of dances with the Plains tribes to the west, where these dances are usually practised by military societies. Among the Eastern Sioux, however, it is exceedingly difficult to determine whether the dances are performed by definite organizations or merely by a congregation of membership varying from dance to dance. The idea is prominent that some one individual, who has had a corresponding vision, must see to the performance of his particular dance, on pain of being struck by lightning if he failed.

#### *Plate Armor in America, a Sinological Contribution to an American Problem:* BERTHOLD LAUFER.

The paper is chiefly intended as a contribution to the much-ventilated question of historical methods applied to ethnology. Plate armor in northwestern America and northeastern Asia was hitherto believed to be due to contact with Japan, and interpreted as having been made in imitation of iron plate armor. From two important passages occurring in the Chinese Annals it becomes evident that bone plate-armor existed among the Su-shên, a tribe of presumably Tungusian stock, in the first centuries of our era, and the conclusion is reached that such armor can not have been made in imitation of Japanese plate-mail, which did not exist at that time. Also in China, Siberia and Korea, iron armor is not very ancient and develops almost contemporaneously with bone armor, which, however, is older than iron plate armor. It is pointed out that plate armor occurred also in western Asia and other ancient culture-groups, contrary to previous opinions, so that the problem is not truly historical, but rather amounts only to a technical question. The imitation theory, therefore, is highly improbable, and the independent origin of plate armor in the north Pacific culture-group must be maintained. Japan has never had any influence on the latter nor on American cultures, and American-Asiatic culture relations and exchanges must be studied in the light of the ancient ethnology and archeology of that region—particularly northern Manchuria and Korea—which remains to be reconstructed in the future.

*The Development of Ancestral Images in China:*

BERTHOLD LAUFER.

The object of this paper is to show that the so-called ancestral wooden tablets serving at the present time in China for the worship of ancestors have developed from a former and very ancient concept of anthropomorphic ancestral images. The present mode of worship is briefly described, and the coexistence of tablets, conventional paper images and portraits is pointed out. The development of family ancestral worship is traced to the times of antiquity and explained as having its origin in hero and clan-ancestor worship, in the cult of which stone and wooden images were employed. These were, in course of time, transferred to the individual family ancestors. After a clear distinction between gods and ancestors had been reached, the images were reserved for the gods, the conventional tablets for the ancestors who, under the influence of the growing democratic tendency of this institution, themselves became more and more conventionalized.

*The Separate Origins of Magic and of Religion:*

JAMES H. LEUBA.

Three types of behavior have been developed by man:

1. The mechanical behavior is the method of dealing with things. It implies a quantitative relation between cause and effect.

2. The anthropopathic behavior includes (a) the common relations of men and animals with each other, and (b) those of men with unseen beings. When these beings are gods, we have religion.

The desired results depend upon an agent endowed with intelligence and feeling.

3. The magical or coercitive mode of behavior, in which neither quantitative nor anthropopathic relations are involved. But magic may be used upon a personal agent. In that case the agent is neither prayed to, nor conciliated by offerings, but coerced.

Most of the varieties of magic may be accounted for by the following principles of explanation:

- (a) Playful prohibitions. "If you do this," say our children, "that will happen to you." The "this" and "that" have usually no logical connection. Playful prohibitions may be taken in earnest and acquire a magical significance.

- (b) Threats of untoward happenings made for the purpose of preserving things vital to the life and prosperity of the tribe.

- (c) The motive which leads people to make vows.

- (d) The spontaneous response of the organism to specific situations. The magical dances had probably this origin.

- (e) The deliberate treatment of certain situations according to magical principles, for instance, that like produces like. This source of magic is, of course, relatively a late one, since it presupposes that a principle of magical procedure has been disengaged from magical practices.

With regard to the origin of science, Leuba maintains against Frazer, that the ancestor of science is not the magical but the mechanical behavior. The essential presupposition of science is that definite and constant quantitative relations exist. The clear recognition of that proposition means, whenever it appears, the death of magic and the birth of science. This fact indicates the opposition of the magical to the scientific attitude.<sup>1</sup>

*Man and the Glacial Period in Kansas:* N. H. WINCHELL.

The paper describes the topographic features of northeastern Kansas, relation of the continental moraine of the Kansan epoch, distribution of human stone implements with respect to the moraine and the terraces. It specially bears upon the patination of the artifacts, as indicative of the glacial age of the agent that formed them, calling attention to the similarity of these specimens to European paleoliths, and enumerating the kinds of implements that carry the distinctive patination, pointing out the succession of cultural stages that preceded the Neolithic and illustrating the contrasts which they present when compared with the Neolithic.

*Evidences of Man's Great Antiquity:* GEORGE GRANT MACCUDRY.

A brief summary of the author's work in Europe during the past season and of the most important recent discoveries: the human remains of a very early type from Sussex; a Monsterial industry associated with a warm fauna (*Elephas antiquus*, *Rhinoceros merckii*, *Hippopotamus*) in the low (fourth) valley terrace at Montières, near Amiens; Torralba, an old camp site near the crest of the Sierra Ministra, Spain, where eolithic and paleolithic implements have been found intimately associated with the remains of *Elephas antiquus* (perhaps also *Elephas meridionalis*),

<sup>1</sup> See for developments Parts I. and II. of Leuba's book, "A Psychological Study of Religion; its Origin, Function and Future," Macmillan, 1912.

*Rhinoceros etruscus*, *Equus stenotis*, and two species of deer; the cavern of Castillo near Puente Viesgo, Spain, with its twelve relic-bearing horizons; Mousterian caves on the Island of Jersey; La Ferrassie, La Combe and Laussel (Dordogne); and the newly discovered cavern of Tuc d'Audoubert (Ariège), with its wall engravings and figures of the bison modelled in clay. The paper was illustrated by numerous lantern slides, for the most part in color.

*The Carayan, Caririan, Chavantean and Guatoan Linguistic Stocks of South America:* ALEXANDER F. CHAMBERLAIN.

Among the less well-known linguistic stocks of the South American Indians are the *Carayan*, *Caririan*, *Chavantean* and *Guatoan*, the first three of which are entirely, and the last particularly, within the area of modern Brazil.

1. *Carayan*.—The present center of the territory of the *Carayan* linguistic stock is on the Rio Araguaya and its affluents in the Goyaz country, south-central Brazil. The chief "tribes," or rather local divisions, of the Carayá are the Chambia, the Javahé and the Carayá proper, the last consisting of two "hordes," a northern and a southern. Our best authorities on the Carayan stock are Coudreau, Ehrenreich, von den Steinen, Kissenberth and F. Krause, the most valuable material (a long Carayá vocabulary and one of over 100 words in Javahé) being found in Krause's "In den Wildnissen Brasiliens" (Leipzig, 1911). Coudreau, in his "Voyage au Tocantins-Araguaya" (Paris, 1897) gives a Carayá vocabulary of 380 words. Older vocabularies are given in de Castelnau, von Martius, etc. The family name, *Carayan*, is derived from Carayá, an appellation by which these Indians have long been known. Krause (p. 187) says that the Carayá proper call themselves "käräjä", kärädjá' and also krädjá."

2. *Caririan*.—The territory of the *Caririan* linguistic stock originally included a considerable portion of eastern Brazil, in the provinces of Bahia, Pernambuco and Piauhý, north, south and west of the Rio São Francisco. These Indians were Christianized in the middle of the seventeenth century, but at most a few hundreds now survive in the valley of the lower São Francisco. With the Cariri proper belong also the Sabuyá, who dwelt somewhat further south. Our chief sources of information concerning the Carayan language, besides the older missionaries (Mamiani, de Nantes, et al.), are von der Gabelentz, Galvão,

Platzmann (who have all republished or edited catechisms and grammars of the missionaries), Adam, Ehrenreich and von den Steinen. A Sabuyá vocabulary of over 100 words is given by von Martius. The family name, Caririan, comes from the appellation of the northern section of this stock, which appears variously as Cariri, Cairiri, Cayrirí, Kiriri, etc. The etymology is unknown.

3. *Chavantean*.—The territory of the Chavantean linguistic stock lies in the region of the upper Paraná and lower Parapanema (about 20° s. lat., 52° w. long.), in São Paulo, Matto Grosso and Paraná (Brazil). These "Chavantes" (v. Ihering seeks to call them "Eo-Chavantes") are not to be confused with the Tapuyan "Chavantes," or "Akua," of Goyaz and Matto Grosso. The linguistic material of the Chavantean stock consists of two short vocabularies by T. M. Borba and F. R. Ewerton-Quadros, both of which are reprinted by Professor H. von Ihering, our chief authority, in his "The Anthropology of the State of S. Paulo, Brazil" (2d ed., S. Paulo, 1906). The family name, Chavantean, comes from "Chavantes" (the etymology of the word is uncertain), a term applied to several Indian peoples of this region.

4. *Guatoan*.—The territory of the Guatoan linguistic stock includes part of the northern Chaco and the region about the confluence of the Paraguay and the São Lourenço, particularly the country about Lakes Gaiba and Uberabá. The Gaiba have been visited and described by Kowalsky (1894), Monoyer (1905), Schmidt (1900-01 and 1910). Our chief authority is M. Schmidt, whose interesting book, "Indianerstudien in Zentralbrasilien" (Berlin, 1905), contains a section on word-formation, a long classified vocabulary, some sentences, etc. An older vocabulary of 160 words is reproduced in von Martius from de Castelnau. Schmidt's résumé of his expedition of 1910 is to be found in the *Zeitschrift für Ethnologie* for 1912. The family name, Guatoan, comes from Guató (Vuató, Quató, etc.), the name by which these Indians have long been known. No satisfactory etymology is on record.

*Material Relating to Californian Indians in E. Teza's Saggi Inediti di Lingue Americane* (Pisa, 1868): ALEXANDER F. CHAMBERLAIN.

Professor Emilio Teza's "Saggi Inediti di Lingue Americane" is so largely taken up with

"Saggi Inediti di Lingue Americane. Appunti Bibliografici." In Pisa. Dalla Tipografia Nistri. MDCCCLXVIII, pp. 91.

the consideration of South American Indian languages that the material therein relating to certain Indian peoples of North America seems to have been rather overlooked. Pilling, who, in his "Proof Sheets,"<sup>3</sup> cites Teza, observes (p. 754): "Mainly devoted to South American languages; but contains a brief discussion and a few examples of Algonkin and Iroquois, pp. 14-22. Our Father in Tarasco, pp. 60-62." Through the courtesy of the library of the University of Pennsylvania, Chamberlain has been enabled to consult the copy of Teza belonging to the Brinton collection, once the personal property of that great Americanist. A colophon, at the end, informs us that "the 'Appunti' were published in the *Annali della Università di Pisa*, MDCCCLXVIII., Vol. X.," and that "of this Edition in octavo, to which has been added an Appendix, only LXX. copies were printed, and they are not for sale." It is the "Appendice," occupying pages 77-91 (pages 77 and 78 are blank) of the octavo edition of 1868 that interests us here, for it contains ethnological and linguistic information concerning some of the Indian tribes of California. On pages 80-86, under the heading, "Balli de' Californesi," is printed the Spanish text of an account by "P. Jak" of ball-games and dances of certain Californian Indians. Those mentioned are: "Jumos, apaches, dieguinos christianos, sanluisenos, que somos nosotros, sanjuanenos, gabrielenos, fernandinos; y los de Monte Rey." The Luiseños are to play well the ball-game of *uauquis*. One game is termed general, and "nosotros llamamos tannis, bailar, o mejor dar patadas." On pages 81-84, 84-85, 85-86 are given, respectively, descriptions of the "Primer baile," "Segundo baile," "Tercero baile." A number of Indian words are scattered through these descriptions. On pages 87-91 are given the native texts and Spanish versions of "Versi Californesi"—two poems composed by P. Jak in the Indian language (the translations are also by him). The dialect represented is probably Luiseño.

Pages 22-30 of the "Saggi Inediti" are also concerned with Californian Indian languages, and on pp. 24-26 P. Jak discusses the grammar of Luiseño. On page 23 we are informed that P. Jak had composed a "Prima lingæ Californiensis rudimenta," ca. 50 pages, and containing "a little of everything." The chief source of infor-

<sup>3</sup>"Proof Sheets of a Bibliography of the Languages of the North American Indians," Washington, 1885.

mation was "a Californian of S. Luis, converted to Christianity," and the thing was done "to please Cardinal Mezzofanti." Teza's whole book, of course, owes its existence to Mezzofanti's linguistic collections.

*A Note on Child-invention:* ALEXANDER F. CHAMBERLAIN.

That invention (conscious or unconscious) by children, with subsequent adoption by adults of the community, has played a not unimportant rôle sometimes in the development of human culture is a theory known in ethnological literature, especially in connection with the evolution of language (von Martius, Peschel, Farrar, Newell, Hale, Krauss, Sartori, Lasch, et al.). The inventiveness of children in plays and games has also had some influence upon primitive society and even upon its civilized successors. Chamberlain has already discussed some aspects of "child-invention."<sup>4</sup> Sel- dom, however, is one fortunate enough to be present when such an addition to the stock of human knowledge is actually being made. The chronicling of such events by travelers and ethnologists among the more or less primitive peoples still in existence is a matter of interest to the historian of human civilization. A curious example of "child-invention" is reported by A. de Calonne Beaufaict, in his recent book of African studies,<sup>5</sup> in writing about the people of the islands of the Uélé, above the Mokwangu rapids, in the northern Congo country.

After calling attention to the fact that the mentality of these Bakango Negroes is not at all of such a stagnant and passive sort, as, e. g., M. Goffin attributes to them in his "Pêcheries et Poissons du Congo," by virtue of which they "must be incapable of taking advantage of and permanently acquiring for themselves the thousand and one little accidental inventions, which, in normal times, pass unnoticed, but to which every critical period gives a special value," and stating that he has often had the opportunity to observe just such cultural acquisitions, the author says (p. 56, footnote):

"One of the most amusing was the invention by a young Mobenge of a bolas to catch fowl. He was gravely imitating angling, with a stick and a *liana*, to which was attached a corn-ear

"See "The Child and Childhood in Folk-Thought" (New York, 1896), pp. 249-269 and 273-275.

<sup>5</sup>"Etudes Bakango" (Liège, 1912). See p. 56 and footnote.

serving for a fish. One of his brothers came running along, in pursuit of the fowl that had to be safely shut up away from the little carnivora. The boy held out his stick, to cut off the retreat of the frightened fowl, which got entangled in the liana, fell down, and was captured. Put into good humor by this grotesque accident, the inventor made a second successful attempt. The next evening, the family were supplied with the apparatus; and my boys imitated it. And, perhaps, in a few years, some descriptive ethnologist will report that the Mobengé used the bolas, and, from that fact, will infer some ethnological theory as to the origin of the tribe."

This example is of more than ordinary interest, since it involves not merely "child-invention," but likewise transference from one form of culture-activity to another—from fishing to bird-catching.

*Description of the Tsantsa.*<sup>a</sup> H. NEWELL WARDLE.

A macroscopic description of one of the rare mummified heads of the Jibaros of Ecuador, with considerable detail as to color, form, size and ornamentation together with the weave of the suspension cord.

*The Principles of Limited Possibilities in Ethnology.*<sup>†</sup> A. A. GOLDENWEISER.

In the present state of ethnological enquiry the reality of convergent developments can no longer be doubted. The actual demonstration of such convergence on general theoretical grounds, therefore, seems highly desirable.

The principle of limited possibilities implies that whereas the origins of cultural processes are innumerable, the processes soon become reduced to a relatively smaller number of types, while the relatively stable products of these processes are strictly limited in number, owing to the play of certain objective and psychological factors. If that is so, there must be convergence. The principle of limited possibilities is thus constituted *a priori* argument for convergent development.

*Three Forms of the Human Nose.* ROBERT BENNETT BEAN.

The three most distinct forms of the human nose appear characteristically in different parts of the earth and the forms are clearly geographical, evolutionary and developmental. The first of

the three is the underdeveloped *nosé* resembling that of the infant, and this form has been called by Dr. Bean the *Hypo-phylo-morph*; the second is a massive nose, the *Meso-phylo-morph*; and the third is the thin, high, long, narrow nose, the *Hyper-phylo-morph*.

The *Hypo-phylo-morph* nose is flat, broad and short, with flat depressed bridge, upturned tip, and the nostrils open forward rather than downward. The nostrils flare and are wide open, and the extremity may be inserted horizontally along the floor of the nasal fossa without interference by the *alæ*. The nasal ridge, or the bridge of the nose, is flat, because the nasal bones do not form a steep roof over the nasal passages by their opposition along the median line. The articulation of the nasal bones with the frontal bone is a gentle curve and not an abrupt transition. The supraorbital ridges and glabella are not prominent, nor the frontal sinuses large in association with this form of nose, but the cheeks are full, and the eyes prominent, therefore the front of the entire face is somewhat flat, although the lips project from a small mouth. The *Hypo-phylo-morph* nose is essentially the nose of the infant.

The *Hypo-phylo-morph* nose is found especially among the Malays and Negritos as they exist to-day in the Malay peninsula, Java, Sumatra, Borneo, Celebes and the Philippine archipelago, as well as among the Pigmies, Bushmen and Hotentots of Africa. It is also found in a modified form in Burma, Siam, Cambodia, Tonkin, Annam, in India, China, Japan, Mongolia and among the true Negroes of Africa and America. The form dwindles away through Siberia, Lapland, Finland and Russia into Europe, where the *Hyper-phylo-morph* nose appears. The form also dwindles away through the Eskimos and Indians of the Americas, among the Polynesians and the other inhabitants of the Pacific Islands and among the pseudo-negroes of north and east Africa, in all of which peoples the *Meso-phylo-morph* nose appears. It is most emphatic among the women of all the countries where it appears, but is also to be seen among the men.

The *Meso-phylo-morph* nose is massive, long and broad, not very high, with apparently depressed root due to overhanging brows and glabella, it has a straight bridge and nostrils that open downward and slightly forward. The outlines of the nose are usually straight. Looked at from in front the lines of contact of the nose with the face on each side are straight, and slant

<sup>a</sup>To be printed in the *Proceedings of the Academy of Natural Sciences*, Philadelphia.

<sup>†</sup>The paper appeared in full in the *Journal of American Folk Lore*, September-December, 1912.

away widely from the inner angles of the eyes to the *alæ* of the nose. Looked at from the side the bridge of the nose is straight or very slightly aquiline from root to tip, and the lower border (base) of the nose is straight from a point just over the *akanthion* to the tip of the nose, although the tip may dip below this straight line sometimes. This line is not long in relation to the breadth of the nose, but it is absolutely as long as the same line in the Hyper-phylo-morph nose, and may even be longer when the nose is unusually large. The nose looks flat, due to its great breadth, when it is actually a high nose. The *alæ* flare little, although the apertures of the nostrils are large, due to the great width of the nose. The nasal bones form a more acute angle at their apposition than in the Hypo-phylo-morph nose, and they pass abruptly above into the frontal bone, where the overhanging brows and glabella give the root of the nose a depressed appearance. The malar and zygomatic bones are large and project, and the jaws are prominent both in front and at the sides of the face. The orbits are large, the bony sinuses about the nose are of great size and the lips are thick. The result is that the whole face is large and the nose conforms with its surroundings.

The distribution of the primary forms of the Meso-phylo-morph nose centers among the inhabitants of the Deccan and Ceylon, among the Polynesian and the inland tribes of the Philippine Islands, Java, Sumatra, Borneo and Celebes, and it assumes its most exaggerated form among the Tasmanians, Australians, Melanesians, pure Negroes and true Negroes. The form exists somewhat modified among the peoples who have the Hypo-phylo-morph nose, and is especially emphatic among the men, although it appears among the women. It fades away through northern Asia, in central Europe, through southern Asia towards the Mediterranean basin and in eastern and northern Africa, at all of which points it merges into the nose of the Hyper-phylo-morph.

The Hyper-phylo-morph nose is long, high and narrow, with high root, bridge and tip, the nostrils flare but little and open almost directly downward. The nostrils may even open somewhat backward in the exaggerated forms, as in the Jew, for instance. The nose appears prominent and may seem larger than it really is, inasmuch as the jaws are not prognathous, and the brows and glabella do not overhang the nose; the forehead and chin may even recede, leaving the nose pro-

jecting from the middle of the face. The nose may be retrousse, straight, sinuous or aquiline. The retroussee seen chiefly among women, is the underdeveloped, whereas the aquiline, seen chiefly among men, is the exaggerated form of the Hyper-phylo-morph nose. Associated with this form of nose is the long, narrow face and the long, high, narrow head. The distance from the external auditory meatus to the tip of the nose is greater in this form than in either of the others, and this projection of the nose to a pointed tip in association with the high, narrow forehead and pointed chin give the characteristic appearance called by the Australians in derision, "the hatchet-faced Englishman."

The most representative types of the Hyper-phylo-morph nose in its primary form are found in northern Europe, Great Britain and America, among the tall blond Nordics, and this form of nose has been modified around the Mediterranean, where it is extremely fine and thin. Its most exaggerated forms are to be seen among the Jews, Arabs and Gypsies. It is found more or less modified in Asia and Africa along the course of four streams of infiltration. The most intense forms (the most perfect) are in southern Asia and northern Africa, the least intense in northern Asia and eastern Africa. The American Indians present a Hyper-phylo-morph nose of an intermediate form between that of the extreme Meso-phylo-morph and the primary Hyper-phylo-morph. The characteristic Hyper-phylo-morph nose dwindle in purity and frequency through southern Asia and northward through the hearts of the large islands of the Pacific among the inland tribes, except among the Tasmanians, Australians and Melanesians, to the inland tribes of the Philippine Islands, and eastward into Polynesia; through northern Asia into China and Japan, where in the latter place the nose is similar to that of the Mediterranean peoples; through northern Africa into the Soudan to the Guinea coast; and through eastern Africa to the Congo and along the south and east coasts up to the Guinea coast and the Congo again. The peoples who have this form of nose in greatest purity may be enumerated as follows: Danes and Scandinavians, North Germans, British, American whites in the United States and Canada, Spanish, Portuguese, some southern French and Italians, Greeks, Turks, Arabs, Jews and Gypsies. Those peoples among whom modified, yet fairly typical, forms are frequent are: East Indians, Iranians and Turanians.

North and East Africans, Europeans other than those previously mentioned, Chinese, Japanese and Tibetans, Polynesians and Micronesians, and the inland tribes of the great islands of the Pacific, Java, Sumatra, Borneo, Celebes and the Philippines.

The three forms of the nose may appear pure among any people, and in differentiating the three forms in any locality I use the terms Hypo-onto-morph, Meso-onto-morph and Hyper-onto-morph, because in every individual it may not be clear that the form of the nose is due to evolution—it may be developmental. The onto-morph noses are not so strikingly different as the phylo-morph forms, but in any case the Hypo-onto-morph resembles the Hypo-phylo-morph, the Meso-onto-morph resembles the Meso-phylo-morph and the Hyper-onto-morph resembles the Hyper-phylo-morph.

*The Nose of the Jew and the Quadratus Labii Superioris Muscle:* ROBERT BENNETT BEAN.

The peculiar position of the Jew for centuries may account for the origin of the Jewish nose. The shape of the nose depends upon inherent and extraneous influences. The latter do not concern us at present. Of the inherent influences, alterations in the bones of the head and face cause changes in the shape of the nose; increased vascularization of the nasal mucous membrane and the erectile tissues of the nose, as in continued excessive sexual indulgence, may alter the shape of the nose; and the muscles attached to the nose may change its form.

The quadratus labii superioris muscle has four parts, all of which center around the ala of the nose and the base of the upper lip, and from there they radiate towards the eyes in the shape of an imperfect fan. The two extremities of the fan are attached, the one at the root of the nose, the other to the ventral surface of the malar bone. The part of the quadratus muscle attached to the nose is called the angular head, which has two slips, one rising from the nasal bone and inserting into the cartilage and tissue about the ala of the nose; the other rising from the upper part of the nasal process of the maxilla near the inner canthus of the eye and inserting into the skin and fascia at the base of the upper lip midway between the center and the side of the mouth. The angular head has been called the levator labii superioris et alæque nasi muscle, a term that expresses its action. The muscle slips pull the ala of the nose upward and backward, depress the

extremity of the nose and help to elevate the upper lip and deepen the naso-labial groove. The two remaining portions of the quadratus muscle are called the levator labii superioris and the zygomatic minor, which form the infraorbital and zygomatic heads, respectively. They rise from the maxilla and malar bone beneath the orbicular muscle and are inserted into the skin and fleshy part of the upper lip near the corner of the mouth. They pull the upper lip upward and backward and deepen the naso-labial groove. Deepening of this groove gives an expression of sadness, which is intensified by sorrow or grief. Assisted by the great zygomatic muscle and the caninus, the quadratus draws the tissues covering the chin upward and backward, pulls the corner of the mouth in the same direction and deepens the naso-labial groove. This sharpens the chin and makes it appear to tilt upward in the form of a beak. The depression of the point of the nose tilts this member downward and gives it the appearance of an inverted beak. The mouth is at the same time drawn back, and the double beak becomes more emphatic.

The quadratus muscle is said to produce expressions of the face that indicate a great variety of emotions, all of which may be grouped as related to indignation. It is essentially the muscle of disgust, contempt and disdain, which lead to scorn, acknowledging guilt. Discontent follows, with a snarl, sneer and defiance; after which come bitterness, and a menacing attitude, with pride. Indignation, anger, rage and hatred rapidly succeed each other. This complex of emotions may be superseded by sadness, grief or sorrow. That one small muscle group can express so many emotions is almost inconceivable, but upon intimate analysis the nineteen words used to enumerate the emotions expressed by the quadratus muscle are related, or proceed the one from the other in natural sequence.

The expression of the Jew is that which would result from very strong contraction of the quadratus muscle. The nose is depressed, and this is so marked that often an obtuse angle is made at the junction of the cartilage and nasal bones, which leaves the cartilage slanting very little and at times vertical. The nose of the Jew is large, and the depression of the tip increases the prominence of the bridge and adds to its apparent size. The ala looks pulled upward and backward, a furrow is seen around the ala and the naso-labial groove is deep. The upper lip and the corner of the mouth appear pulled upward and backward

and the tissues of the chin are drawn, giving the beaked look. This characteristic is not well marked on all Jews, being more emphatic on some than on others; it is also to be seen on those who are not Jews, but it is more pronounced on Jews than on other peoples, and that it is a Jewish feature can not be doubted. Having become a recognizable characteristic, it was used in sexual selection. Those who showed it most strongly would be selected in marriage by the most orthodox, and would transmit a natural endowment to their offspring. Those who gave less evidence of it might marry outside of the race. In this way the feature became fixed, and it is as such an inheritance as any other characteristic. The peculiar position of the Jew for centuries may account for the origin of the Jewish nose.

The papers read of which the secretary was unable to obtain abstracts were:

*Abnormal Types of Speech in Nootka* (to be published by the Geological Survey of Canada): EDWARD SAPIR.

*Peintre and Nahuatl: A Study in Uto-Aztecan* (to appear in the *Jour. de la Soc. des Américanistes de Paris*): EDWARD SAPIR.

## SOCIETIES AND ACADEMIES

### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

A SPECIAL meeting of the Anthropological Society of Washington was held January 7, 1913, in room 43 of the new building of the National Museum, the president, Mr. George R. Stetson, being in the chair.

Mr. E. Dana Durand, director of the Census, read an important paper on "Race Statistics of the Last Census," replete with interesting facts. Mr. Dana said, *inter alia*, that during the decade 1900-10 the white population of the United States increased about 22 per cent. and the negro about 11 per cent. This difference is partly due, however, to the direct or indirect effect of immigration of whites, in the absence of which the whites would have increased about 14 per cent. The Indians increased about 12 per cent., the Chinese decreased in number, while the Japanese nearly trebled. The whites have at practically every census shown a more rapid rate of increase than the negroes, and there is reason to believe that the difference between the two races in rate of increase from 1890 to 1900 was greater than appeared from the census returns, on account of a probable underenumeration of the negroes in 1890. The census of 1910 showed that about 21 per cent. of the negroes are mulattoes, as compared with about 12 per cent. in 1870, the last preceding census at which the question regarding blood mixture was asked in comparable form.

There has been no very great migration of negroes out of the south, nearly nine tenths of the total number being still found in that section. The number living outside the south increased 167,000 between 1900 and 1910, while the number residing in the south increased over 800,000. The rate of natural increase—that is, by excess of birth over deaths—of the white population of the south, however, is much higher than that of the negroes, being higher also than that of the whites in the north.

Among the native white population whose parents were born in this country, there were, in 1910, 104 males to each 100 females, as compared with only 98.9 in the case of the negroes. Among all classes of the population more boy babies than girl babies are born, but equality tends to be brought about by a higher death rate among the males. The difference in sex distribution between the whites and the negroes is probably attributable, in part at least, to more favorable health conditions among the whites.

The age distribution of the native white population is somewhat different from that of the negroes, probably chiefly on account of a lower death rate among whites, tending to greater longevity. There has apparently been a very marked decline in the birth rate among negroes in recent years, while there has been a gradual but less marked decline in the birth rate of the whites during each decade for a long period of time.

Negroes tend to marry earlier than the native white classes; and, in fact, at all age periods the proportion of married, widowed and divorced persons, taken together, is higher in the case of the negroes of both sexes than in the case of the native whites of native parentage.

There has been a marked change in the composition of the foreign-born population of the United States during recent years. Natives of northwestern Europe constituted more than two thirds of the total foreign-born population of the United States in 1900, but less than half in 1910, while southern and eastern Europeans formed only a little over one sixth of the total at the earlier census, as compared with three eighths in 1910. The Germans and the Irish particularly have fallen off conspicuously in numbers, while the natives of Russia—largely Russian Jews and Poles—Austria, Hungary, Italy, Greece and other countries of southern and eastern Europe have increased by very high percentages, no less than 1,090 per cent. in the case of natives of Greece. The natives of Russia now rank second among the foreign-born classes, and those of Italy fourth.

The speaker answered inquiries of various members as to sundry items, and these questions were accompanied by brief statements contributing further facts and explanations, but there was no extended discussion.

WM. H. BABCOCK,  
*Secretary*

#### THE ACADEMY OF SCIENCE OF ST. LOUIS

At the meeting of the Academy of Science of St. Louis on January 20, Mr. S. Bent Russell read a paper on "Demonstration and Design of Apparatus to Simulate the Working of Nervous Discharges."

Professor J. L. Van Ornum, of Washington University, spoke on "Experiments on the Pointing of Pressure Tubes to Eliminate Velocity Effects in Water Pipes."

Professor F. E. Nipher, of Washington University, communicated to the academy the results of recent experiments which seem to indicate that the strength of a steel magnet depends upon its electric potential. The magnetic moment determined by the Gaussian method of deflection appears to be a maximum when its negative potential is somewhat less than that of the earth.

The magnet consists of a single layer of steel wire having a diameter of .022 of a centimeter wound longitudinally on a hollow conducting cylinder 30 centimeters long and  $2\frac{1}{2}$  centimeters in diameter. The needle acted upon by this magnet is completely enclosed in a copper screen. A mirror on the needle is observed through a glass window covered with copper gauze of .1 inch mesh. The needle is held in the magnetic meridian by means of an ordinary magnet serving to balance the deflection due to the wire filaments constituting the magnet to be tested. This magnet is insulated and connected with either terminal of an influence machine, the other terminal being grounded. No disruptive discharges are permitted to occur.

When the magnet to be tested is connected with the positive terminal of the machine the needle is slowly deflected over an angle of about 4 minutes of arc in about one fourth of an hour. When the magnet is disconnected the needle returns to the zero position in about the same time interval. This may be repeated many times. The magnet becomes stronger while in contact with this terminal.

When connected with the negative terminal similar effects are produced, but the magnet becomes weaker instead of stronger.

When the magnet is freshly magnetized it does not wholly recover its strength when it is enfeebled by connection with the negative terminal, but it approaches a condition of permanence when the operation is repeated.

This result is similar to the well-known fact that the attraction between masses of matter depends upon their electric potential.

Professor Nipher suggested that plating the steel wire, of which the magnet is composed, with a film of non-magnetic matter is likely to lead to results of great interest.

## Saunders' New Books

### Brill's Psychanalysis

APPLICATION OF  
FREUD'S THEORIES

This one volume gives you the practical application of all Freud's theories, and it gives it to you from the pen of a man thoroughly competent to write on this subject. Psychanalysis is the only system of psychotherapy which deals with the neuroses as *entities* instead of treating symptoms, as do hypnotism, suggestion, and persuasion. The results of psychanalysis are most effective. It is only through psychanalysis you can gain a real insight into the neuroses and psychoses. You will find Brill's work most valuable.

Octavo of 337 pages. By A. A. BRILL, Ph.B., M.D., Clinical Assistant in Psychiatry and Neurology at Columbia University Medical School. Cloth, \$3.00 net.

### Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. Not only does this work give the salient facts of structural zoology and the development of the various branches of animals, but also the natural history—the *life and habits*—thus showing the interrelations of structure, habit and environment.

Part I—*Field and Laboratory Guide*: 12mo of 275 pages, interleaved. Cloth, \$1.25 net. Part II—*Principles*: 12mo of 406 pages, illustrated. Cloth, \$2.00 net. By L. S. DAUGHERTY, M.S., Ph.D., Professor of Zoology, State Normal School, Kirksville, Mo.; and M. C. DAUGHERTY, author with Jackson of "Agriculture Through the Laboratory and School Garden."

### Stiles' Nutritional Physiology

This new work expresses the most advanced views on this important subject. It discusses in a concise way the processes of digestion and metabolism. The key word of the book throughout is "energy"—its source and its conservation.

12mo of 295 pages, illustrated. By PERCY GOLDTHWAIT STILES, Assistant Professor of Physiology at Simmons College, Boston. Cloth, \$1.25 net.

## PHYSICS AND DAILY LIFE<sup>1</sup>

THE school system of Germany has often been held up to the teachers of this country as a model of perfection. Germany has been called a nation of schoolmasters, and the wonderful progress of its industries has been attributed in no small measure to the rigid training and high efficiency of its gymnasia, its universities and its vocational schools. Even at the present moment our country is being urged on many sides to establish alongside the regular public secondary schools an independent system of vocational schools, the chief argument in favor of this plan being the fact that it was "made in Germany."

Notwithstanding the fact that the reputation of the German schools is so brilliant on this side of the Atlantic, there are many thoughtful and earnest dwellers in the Fatherland who consider the training given by their schools to be of very doubtful educational value. Thus, some twenty years ago Emperor William II. called a congress of the leading schoolmen of Germany to consider what could be done to bridge the chasm that yawned so wide and deep between the work of the schools and the daily lives of the pupils. Little was accomplished as the result of this congress. The schoolmen declared it were little short of sacrilege to experiment with schools, which had always enjoyed a reputation for perfection equaled only by that of the medieval monks. Since that time, the vocational and industrial schools of Germany have developed alongside and, in large

<sup>1</sup> Presented at the conference of the University of Illinois with the secondary schools of the state, November 22, 1912.

measure, independent of the "regular" schools. This unfortunate double system of public schools was made necessary because of two relentless and irreconcilable facts: namely, (1) the needs of the people; and (2) the "conservatism" of the schoolmen.

In spite of the fact that the vocational schools of Germany did bring education and life nearer together for the working classes, the children of the intellectual classes continued their double existence in the world and in the school respectively until very recently. Day has, however, now begun to dawn on the academic landscape, and efforts, which originated among the teachers of science, are now being made to establish some semblance of a relationship between the school routine and the daily lives of the pupils. The evils that are being eliminated are over-systematization, rigid uniformity and the belief that words, signs and symbols can be made to serve in the educational process in place of concrete materials and real problems.<sup>2</sup>

Many will doubtless recognize the similarity between the experiences of Germany and those through which this country is now passing in the matter of bringing school and life to have something in common besides the children themselves. The needs of the masses for vocational schools are only equaled by the needs of the pupils in the regular schools for mental pabulum that nourishes them and helps develop their characters. Can you doubt this in the face of trustworthy reports, like that of the City Club of Chicago, which show that the present public school system fails to reach more than half of the school population? If so, study the statistics of elimination and re-

tardation and be impressed by the enormous annual waste in material resources thus caused—the much more impressive and disastrous waste in human resources can never be calculated.

In this state of Illinois, as you all know, the crisis is imminent. The state legislature is considering a bill for the authorization of a second independent system of schools, intended in some measure to atone for the shortcomings of the present public schools. The chief argument in favor of the proposed plan is that the schoolmen who are now in control are both incompetent and unwilling to reorganize their work so as to meet the needs of that half of the school population which is not benefited in any marked degree by the present system. In support of their argument, Germany is held before us as a model, and we are urged that, as it is in the Fatherland, so must it be here. In other words, the incompetency of the teachers in permitting the proven inefficiency of the schools to continue is condoned, and we are invited to authorize additional expenditures on the ground that others, not schoolmen, can succeed where we have failed.

What would a captain of industry think of an analogous proposition with regard to his manufacturing plant? Suppose that a plant and its employees wasted half of the raw material supplied to it; would the manager enlarge the plant and take on more hands of a different sort in an endeavor to reclaim some part of the original waste? Yet the idea is abroad that this sort of a procedure, obviously absurd in an industrial enterprise, is, nevertheless, justified in school practise. The basis for this idea seems to be the fact that teachers are supposed to be so conservative that they are unwilling even to consider a new idea, much less to adopt it.

We teachers, naturally enough, repudi-

<sup>2</sup> Ostwald, "Wider das Schulelend," Leipzig, 1909; Gutzmer, "Die Tätigkeit der Unterrichtskommission der Gesellschaft deutscher Naturforscher und Aerzte," Leipzig, 1908.

ate this accusation. We pride ourselves on being the most progressive of all people. Do we not all use our last bit of strength to keep up to date? Yet, where there is so much smoke, there must be some fire. It behooves us then not merely flatly to deny the charge, but rather to analyze carefully our methods and results in the effort frankly to discover wherein we have given ground for popular misconceptions.

This analysis might be found to be a difficult, not to say embarrassing, undertaking if it were not that the problem may be stated in a somewhat different way which permits of a ready answer. Instead of asking what grounds we have given for a reputation of ultra-conservatism, we may ask whether we have as yet succeeded in bringing the school work close to the lives of the pupils. After graduation our education and our lives are most inextricably entangled. Is it so before graduation? For if it is, the problem of vocational education vanishes. If the life of the child is his education, or if his education is his real life, he is developing to serve society to the full extent of his abilities. But if this is not true, if his schooling and his life are to him two strangely incompatible forms of existence, then there is something radically wrong with the school. Are we then making education and life a unified existence for the pupils?

The answer to this question must be an unequivocal *No*. The simple fact that this conference and other similar conferences all over the country are considering how to bring schoolwork close to child life is complete proof of the correctness of this answer. We teachers stand convicted by our own acts. We recognize that we fail at this vital point.

But even though we fail, are we willing and ready to improve and constantly to work for a closer union of education and

life? Here the answer is equivocal: some are, and some are not. Some are willing to try, but are placed in circumstances where they are not free to make the effort. They are blocked by the authority that works from above downward—particularly the latter. Others express in words their willingness to make the trial, but continue in deeds to run along in the same old rut. Still others are eager to break away from the present system and to strive for a more efficient one, but they do not know where to begin. In the hope of helping such as these in gaining a vantage-ground from which to work for the union of education and life, the following hints are given. They constitute a brief summary of the main points of agreement among those who have in some measure succeeded in breaking loose from tradition and from the vested interests of school paraphernalia and equipment.

The first of the false gods that holds and will forever hold education and life asunder is the idol of uniformity. How this graven image ever came to be given an honorable place in the temple of learning passeth all human understanding. The genius of a man, the characteristics that mark him off from his fellow men and give him his priceless personality, are his individual differences. It is because he has traits and combinations of traits which are different from those of any other man that he is interesting and powerful or weak, as the case may be. In life, it is his individual differences that mark him for success or failure, but in school these must be ignored and blighted. "Every one is best trained for his greatest usefulness in life by destroying his individual differences, by putting him through the same intellectual mill with every one else"; so says the idol of uniformity.

The absurdity of this idea in general needs not to be expanded here. It has

been recognized, and efforts have been made to suppress it as far as programs of study go. Thus there are the classical courses, the scientific courses, the technical courses, each of which is supposed to minister to a definite type of mind. But here again the idol has but been broken into smaller pieces, each fashioned after the form of the whole. This arrangement has again proven unsatisfactory, and the elective system has done much to shatter it. A perfectly rigid course is found at present only in highly specialized professional schools.

But the idol of uniformity still persists in the specifications of each single course. It is manifestly so great an administrative convenience to have a unit of physics mean the same thing—at least superficially—whether the work is done in Florida or in Oregon. So the idol has been shattered into still smaller fragments and each of these, fashioned in the likeness of the original, sits enthroned in some class-room. In this diminutive, unobtrusive, almost unnoticed form, the idol still holds sway over the greater part of the work of the schools. We have become so used to him that we do not recognize the fact that he sits between us and our goal, and effectively prevents our bringing about the long-sought union between education and life.

Is it any less absurd to suppose that every class in physics can be taught successfully in one set way, than it is to imagine that every mind can be trained successfully by the same grind or every malady cured by the same treatment? The experiences in the lives of the children of New York City and of those in Urbana are very different. Can one and the same physics be doled out to both with any hope of bringing physics close to the daily lives of both? Certainly not; any more than you can grow oranges and bananas at the North Pole. Then why

do teachers usually take great pride in the nearness with which their course coincides with the standardized forms set up by social convention in defiance of the natural processes of the youthful mind? Were it not far better to take pride in the close adaptation of a course to the needs of the environment in which it is given? Hence the first essential for bringing physics close to the daily life is that the teachers free themselves from the servitude of this idol of uniformity. We must become iconoclasts long enough to smash these diminutive images into fragments.

The *credo* of the idol of uniformity is the syllabus. Strange as it may seem, there are numerous syllabi, all claiming to be authentic. When not enforced by some *pontifex maximus* of the idol of uniformity, these syllabi are fairly harmless. Their chief danger lies in the fact that they tend to focus the attention of teachers on subject matter. In this the syllabus is a just possession of the idol of uniformity, since the latter is only an image, possessing, it is true, the form of a man, but devoid of life, of soul, of spirit. Therefore following the precepts of a syllabus gives a merely superficial uniformity—it creates an external resemblance among physics courses, but does not necessarily assure them an inner similarity, a spirit of investigation, clear judgment, scientific imagination, or unity. In the matter of bringing education close to life, syllabi are as useless as the idol that inspired them.

Once we have freed our minds from the obsession of the idol of uniformity, we are ready to advance to the organization of a course of study that will have some chance of bringing physics and the daily life of the pupils who are to pursue it into close union. It is, however, useless to make outlines until we are well rid of the idol. Assuming that this has been accomplished,

there is one characteristic of the course which is of the most fundamental importance for the purpose in hand, and this is what may be called the philosophy of the course. This determines the point of view or general attitude toward the subject and also settles the method of presentation. Taken as a whole, the philosophy determines the value of the course as a contribution to the mental development of the pupils. If this philosophy is of the right sort, the choice of subject matter is of secondary importance; for then physics enters into the pupil's life as an integral part and creates an attitude toward science and an ability to solve problems scientifically. This attitude and this ability once secured, the pupil will be able to read and experiment intelligently for himself and so to extend his knowledge of the subject as occasion may require. We will try to define this philosophy in such a way that teachers may be helped in discriminating between a weak course and one likely to be of great strength in uniting education with life.

The idea that there is such a thing as the philosophy of a course of study is probably new to most schoolmen, because syllabi and college entrance requirements have so accustomed us to look only at the external form or index of subject matter as defining the excellence of a course that we have failed to notice its far more important internal organization. For the sake of making clear what is meant by the philosophy of a course, and in the hope of attracting your attention to this most fundamentally weighty problem, three types of philosophy of physics courses will be briefly outlined.

The first is the old stand-by which was expressed in the college-entrance statement that physics should teach the "laws and principles of elementary physics." With this end in view, the topics demanded by

the college syllabus were sorted out under the heads Mechanics, Heat, Sound, Light and Electricity. The topics that fell under each head were then arranged in what adult teachers considered their order of simplicity. Thus in mechanics, the order was: Centimeter, Gram, Second. These were duly defined without giving the pupil any clue as to what he was to do with them. These simple elements were then compounded in various ways into meters, square centimeters, centimeters per second, grams per cubic centimeter, and so on. The distinction between mass and weight was always carefully made, and each item was carefully memorized so as to be available at the next examination.

In electricity, in like manner, we must begin with the electric charge obtained by rubbing a glass rod with the skin of an unfortunate cat—obscure and pitiful victim of science! Then followed the action of two charges on each other, with descriptions of the various stunts which the two charges could be made to perform—how they could be imprisoned and released, multiplied, divided or annihilated, as the case might be. In all of this the topics were merely described and experiments presented which might serve to illustrate them and make them concrete.

This organization of the course is generally called the "logical" order because it proceeds from what is to the adult physicist simple to what is to him complex. The philosophy back of it may be called the encyclopedic philosophy. In this type of instruction there is usually little unity, no repetition and no problems that are real to the pupils. The victims usually gained from it a hodge-podge of jumbled memories, a few catch phrases which they could not use rationally, and no ability in solving scientifically the real problems of their daily lives.

This method of teaching was dominant in physics courses from about 1890 to 1905. During this period physics justly became one of the most unpopular subjects in the high-school curriculum. Since 1905 its influence has rapidly declined for two reasons: namely, first, it overreached itself by so increasing the number of topics included in the course that it became impossible for the pupils to make even a faint pretense of memorizing them all; and second, the physics teachers themselves came to realize its inadequacy and arose in revolt and overthrew it.

The chief reasons for its inadequacy were these: (1) It gave no unity to the course, since it failed to group the topics about the great principles of physics but contented itself with the superficial classification of subjects under the heads mechanics, heat, and so on. On this account, it gave little chance for the repetition which is so necessary for the successful mastery of a subject. It also furnished little perspective among the large range of topics treated. Artesian wells seemed to the learner as important as the principle of action and reaction. (2) It took slight account of the daily lives of the pupils. Physics was a "disciplinary" subject, forsooth, like mathematics and Latin, and the more distasteful it was to the pupils the greater the benefit derived from it. (3) It conceived the mission of physics to be didactic—to teach the pupils the last word on each topic—rather than to help them to solve problems of their own making. Principles and facts were merely stated, explained, illustrated with strange experiments, and applied to utterly abstract problems like finding the number of dynes that would give a mass of ten grams an acceleration of ten centimeters per second. On this account it failed to appeal to the pupils, so that they were not motivated to act on their own initiatives.

Fortunately for the children, this encyclopedic philosophy has been, as stated, rapidly declining in influence since about 1905. There are at present two other philosophies, very different from each other, which are striving to replace it. The physics teacher must choose between these two, since he can not adopt both. The first of these is not so very different from the older one. Its motto may be expressed in the words: "The first course should give the pupils a general survey of the whole field of physics." In accordance with this motto, it advocates including in the first course something of everything, thereby retaining the old fallacy of too many topics. It, however, seeks to unify the topics by stringing them on the large theories and hypotheses of physics. Thus, the pressure of gases, evaporation, expansion by heat and electrolysis are not isolated phenomena, but are nothing but the results which the normal actions of molecules and atoms would, of course, produce. The phenomena of light do not consist of the familiar facts of vision, but are evidently and simply the effects which any one would expect electromagnetic undulations in an imponderable luminiferous ether to produce. The pupils need not learn clearly and definitely what light actually does in their daily lives, but rather must master the mechanisms which genial physicists have constructed to aid them in picturing how these effects might be brought about.

In this method the daily lives of the pupils plays a relatively subordinate part. Familiar experiences are introduced after the clever mechanisms of the wily physicists have been duly set forth. For example, all matter consists of molecules in motion. When a dish of water stands on the table, the molecules of water under the surface are more crowded together than those above the surface. At the surface

water molecules are flying off into the air and back from the air into the water. But under these conditions more molecules fly from water into air than the reverse; hence the water gradually disappears from the dish. Heat is nothing but molecular kinetic energy. If the water is heated, evidently the kinetic energy of the water molecules is increased. They therefore disappear into the air more rapidly than before, and the dish dries up more quickly. If a bell jar be placed over the dish of water, the molecules of water can not spread over the entire room, but are constrained to butt their heads against the jar. We should expect these impacts to produce a pressure on the inner walls of the jar. After a time a condition is reached in which just as many molecules fly from the water into the air as fly from the air into the water. Then evaporation should cease. We find that it does so. Under these conditions the water vapor in the jar is said to be saturated.

This second method of teaching thus seeks to interpret phenomena to beginners not in terms of immediate concepts like wet, dry, pounds, inches, pressure and the like, but in terms of less immediate abstract concepts like molecules, atom, imponderable ether, and so on. Here, again, the effort is made to impress on the pupils conceptions and interpretations which may be wholly concrete to specialists in physics, but which are totally abstract to beginners, especially those of school age. For this reason this type may be called the theoretical or abstract method.

It will be noted that this theoretical or abstract method has much in common with the encyclopedic philosophy, especially as regards method of presenting topics. It is of necessity didactic in spirit, since it proposes to impose on the pupils, not the laws and principles of physics, but a survey of

the whole field, consisting in the last analysis of the theories and working hypotheses of physics. It, therefore, does not encourage originality, initiative and creative imagination, since the system which it seeks to implant has already been worked out by the masters and is so comprehensive that the pupils have to be crowded in order to cover it all in the allotted time. The pupils are thus very apt to pick up the terminology of the system long before the terms stand for anything really concrete to them and they use this terminology freely to cover up their real ignorance of how best to control the forces of nature under a given set of real conditions.

In the courses of this type you will seldom find a topic introduced by a daily experience or by a problem that arises from daily experience. These, to the pupils real and concrete things, are usually placed last under the head of applications. You will often find in these courses topics introduced by laboratory or lecture experiments; but most of these are, for beginners, little less abstract than the dynes, atoms and unit poles into which they are deftly resolved by the teacher. A thing is not concrete to a pupil merely because it is made of matter; it is concrete only when it easily associates itself with the concepts and ideas already present in his mind as the result of his previous experiences.

The abstract philosophy has developed courses that are better organized than the older courses, in that they possess greater unity. They suffer, nevertheless, from many of the faults of the former because they overemphasize the value of physical theory to beginners, and so seek to impose a ready-made system on the pupils without justifying this procedure in advance. Whatever advantages this method may be supposed to have in preparing pupils for later work in some colleges and technical

schools, the over-emphasis of physical theory carries with it an under-emphasis of the daily experiences, and this renders courses of this type little adapted to bringing physics close to daily life. Those who adopt this philosophy may not expect to contribute much to the solution of the problem before us. Their work but adds weight to the demands of that vast majority of our people who must earn their livelihood by controlling the forces of their physical surroundings and solving life's practical problems in the most scientific way.

The other philosophy which is now contending with the abstract for a controlling voice in the organization of physics courses for beginners is quite different from that just discussed. This third system places neither the laws and principles of physics, nor yet the theories and hypotheses of the science at the center of its system. Instead of these human interpretations of phenomena, it centers its ideas about the development to the utmost of the powers and latent abilities of that hope of the future of our nation, the human child himself. It holds that physics does not exist in the schools for the purpose of familiarizing young people with either the laws or the theories of physics; but rather for the sake of helping the pupils to increase their powers of controlling their physical environment intelligently and solving their life's problems rationally. If this help is wisely given, they will, of course, learn the most fundamental facts and generalizations of physics; and they will learn them not as theoretical mechanisms which may help them to imagine how phenomena might be "explained," but as practical knowledge which will help them to control the forces of nature in daily life. Because of the nature of its central idea, this type may be called the practical or concrete philosophy.

This concrete philosophy demands a very

different method of treatment from that developed by the other two. The most important differences consist in introducing each topic by means of daily experiences of the pupils of each class, in discussing these topics at the outset by the methods of reasoning with which the pupils are already familiar, in working in both class room and laboratory with materials and apparatus which are in common use outside of physics classes, and in leading to conclusions which are expressed in concrete terms, like pounds and feet, rather than in abstract terms, like atoms and ether.

This method thus takes the child as he is, and seeks to enlarge his fund of information concerning what the things about him will actually do, and to increase his powers of controlling his physical surroundings. Signs and symbols are not introduced until a need for them has arisen and the ideas for which they stand have become fairly concrete by wide association with previous concrete ideas. Theories are not expounded until the pupils have acquired a broad and definite knowledge of the facts and laws which the theories are invented to explain.

The concrete philosophy thus demands an arrangement which begins where that required by the others ends, namely, with the daily life; and ends where the others would begin, with the laws and theories of physics. It lays great weight on having the pupils at the beginning of their course work much with familiar things in ways familiar to them, and insists on their solving many problems of their own making by experiments with apparatus and machines of the sort used in the world's work. It seeks to lead the pupils gradually from the crude intellectual manners with which they come to the physics classes to the more refined and rigorous methods of think-

ing with which they should leave them, at the same time gradually increasing their fund of concrete, definite, dependable and useful information.

This method makes it possible to master fewer principles in a given time; but, as the psychologists have conclusively proved, assures the pupils of a much greater chance of retaining both the subject matter studied and the methods of reasoning used as real helps in solving the real problems of later life. In other words, the method demanded by the practical philosophy is the one that assures us of giving the greatest amount of transferable training.<sup>3</sup>

In order to fix in mind the differences among the three types of method just described, the following three samples of treatment are given. They are typical of the way in which the subject of light may be introduced in accordance with the three types of physical philosophy.

I. *Encyclopedic*.—A luminous body is one that emits light. A medium is any substance through which light passes. A transparent body is one that obstructs light so little that we can see objects through it. A translucent body is one that lets some light pass, but not enough to render objects visible through it. An opaque body is one that does not transmit light. A ray of light is a single line of light. A pencil or beam of light is a collection of rays, which may be parallel, diverging or converging; it may be traced in a dark room into which a sunbeam is admitted by the floating particles of dust which reflect the light to the eye.

The visual angle is the angle formed at the eye by rays coming from the extremities of an object. Knowing the distance

of a body, we immediately estimate its size by the visual angle.

Laws of Light. (1) Light passes off from a luminous body equally in all directions. (2) Light travels through a uniform medium in straight lines. (3) The intensity of light decreases as the square of the distance increases.

II. *Abstract*.—Just as sound is defined as undulations in the air, or some other medium, that produce the sensation we call sound, so light, in the same sense, consists of undulations or waves in a medium that produce the sensation called light. Physicists have agreed to call this medium which transmits light the ether. It exists everywhere, even penetrating between the molecules and atoms of ordinary matter. Nothing is known about its nature and but little concerning the exact way in which light travels through it; but the masters of science generally agree that light is a wave motion in the ether, and that the vibrations of these waves are not longitudinal as in sound waves, but transverse. The transverse disturbances by means of which the waves are propagated are probably not transverse physical movements of the ether, but transverse alterations in its electrical and magnetic conditions.

A transparent body is one which allows light to pass through it with so little loss that objects can easily be distinguished through it. Examples of transparent bodies are glass, air, water. A body is translucent when it transmits light so imperfectly that objects can not be seen distinctly through it. Such bodies are horn, oiled paper, thin sheets of wood. Opaque bodies are those which transmit no light, as brick, pig iron, wooden boards. No sharp line of separation between these classes can be drawn; the classification is one of degree.

III. *Concrete*.—If a number of people

<sup>3</sup> For a more detailed discussion of this point, see Mann, "The Teaching of Physics for Purposes of General Education," Chap. VII-X. New York, Macmillan, 1912.

are asked how large the moon looks, each will give a different answer. One may say that it looks as large as a dime, another that it seems as large as a saucer, while a third may say that it looks as large as a cart wheel. Then, too, the moon looks larger to every one when it is near the horizon than when it is high in the sky.

Infants reach for the moon and cry because they can not get it. Landsmen find it very difficult to estimate the distance between two boats at sea. On the other hand, when we look at a man climbing a distant hill, he appears as but a small speck on the landscape, yet we estimate his size correctly. We even use our knowledge of the man's size to estimate the distance or actual size of the hill or the height of the trees there. Ability to estimate distances and sizes from the way things look is obtained from long practise. Let us see if we can find the reasons for these things.

When sunlight streams through the window, it traces an outline of the window on the floor. If you hold your open hand so that the sunlight falls vertically upon it, the outline of the shadow cast on the floor resembles the outline of the hand. Most of us have amused ourselves making shadow pictures, by so placing the hands between a lamp and the wall that the shadow on the wall resembled a rabbit, a goose, a clown, or any other creature. We might draw the same outline by pivoting one end of a long straight pencil at the source of light, and moving it around the edges of the object, while the other end marked on a paper suitably placed. We can think of such a pencil as if it were the beam from a tiny searchlight moving about the edges of the object and tracing the outline.

When a sunbeam is allowed to enter a darkened room through a small opening, its path, as revealed by the dust particles in the air, is seen to be a straight line.

Where it falls on some object it makes a bright spot. The sun, the opening, and the bright spot all lie on the same straight line; so from inside the darkened room we can determine the direction of the sun with reference to objects in the room, by means of the line drawn from the center of the bright spot through the center of the opening. Because light travels in straight lines, we judge the direction of an object by observing the direction in which light from the object travels.

Whatever you may think of the relative merits of the three types of method just outlined, it is clear that the only way to bring physics close to daily life is to bring daily life close to physics. The only method that assures the teacher of doing this successfully is that of the practical or concrete philosophy. It is possible that other methods may be more successful when the aim is to prepare students to meet past or present college entrance requirements, or to pursue later courses in some of the technical schools. Other methods can not, however, compete with the concrete method when the aim of the teaching is the union of education and life. Each teacher must, therefore, choose his own aim and adapt his methods to suit it. Let me in closing remind you of the importance of the choice. Had education and life been united long ago, the schools would not now stand discredited, nor would the demand for separate vocational schools have arisen. A union now of education and life will save the situation.

C. R. MANN

THE UNIVERSITY OF CHICAGO

ON THE APPEARANCE OF HELIUM AND  
NEON IN VACUUM TUBES<sup>1</sup>

At the last meeting of the Chemical Society, Sir William Ramsay, Prof. Collie,

<sup>1</sup>From *Nature*.

and Mr. Patterson described some experiments which they regard as proving the transmutation of other elements into helium and neon. I have been making experiments of a somewhat similar character for some time, and though the investigation is not yet finished, the results I have obtained up to the present time seem to me in favor of a different explanation from that put forward at the Chemical Society. I described some of these experiments in a lecture at the Royal Institution on January 17, but as the separate copies of that lecture have not yet been issued, I will give here an account of some of the experiments which seem to me to have the most direct bearing on the phenomenon in question.

I used the method of positive rays to detect the gases; this method is more sensitive than spectrum analysis, and furnishes much more definite information. I may say that the primary object of my experiments was to investigate the origin and properties of a new gas of atomic weight 3, which I shall call  $X_3$ , which I discovered by the positive-ray method. This gas, as well as one with an atomic weight 20 (neon?), has appeared sporadically on the photographs taken in the course of the last two years; the discharge in the tube being the ordinary discharge produced by an induction coil through a large bulb furnished with aluminium terminals, and containing gas at a very low pressure. There seems to be no obvious connection between the appearance of either of these lines and the nature of the gas used to fill the tube; the 3 line has appeared when the bulb was filled with hydrogen, with nitrogen, with air, with helium, or with mixtures of hydrogen and oxygen in various proportions; the 20 line when the bulb contained hydrogen, nitrogen, air, hydrochloric acid gas, mixtures of hydrogen and oxygen.

The experiments I made had for their object the discovery of the circumstances which favor the production of  $X_2$ , and to test whether it was triatomic hydrogen produced by the discharge, as this is the alternative to its being a new element. I have found that the conditions which lead to a considerable production of  $X_3$  generally give rise to the appearance of helium and neon. Indeed, in the great majority of cases in which I have observed the appearance of traces of helium and neon these gases have been accompanied by larger quantities of  $X_3$ ; this gas seems to have escaped the notice of the readers of the paper at the Chemical Society. I may mention, too, that along with neon of atomic weight 20 there is a line in these circumstances corresponding to an atomic weight 10 or thereabouts. Though this is probably due to neon with two charges of electricity, it is generally brighter in comparison with the neon line than is usual for the lines corresponding to doubly and singly charged atoms, so that it is not impossible, though perhaps unlikely, that it may be due to a new gas.

The positive rays for the analysis of the gases were produced in a vessel containing gases at a low pressure. I shall call this the testing vessel; the vessel in which the various processes for generating  $X_3$  were tried (the experimenting chamber) was sealed on to the testing vessel, but separated from it by a tap. Thus the pressure in the experimenting chamber was not restricted to being the same as that in the testing vessel, but might have the value which seemed most appropriate for any particular type of experiment. After these experiments were over, the tap was turned and some of the gases from the experimenting chamber let into the testing vessel; a photograph was then taken, and by comparing it with one taken before turning the

tap the new gases present in the experiment chamber could be detected. The processes by which I have hitherto got the most plentiful supply of  $X_3$  are:

(1) By bombarding with kathode rays metals and other bodies.

(2) By the discharge from a Wehnelt kathode through a gas at a low pressure.

(3) By an arc discharge in a gas at a comparatively high pressure.

By far the larger number of the experiments were made by bombarding metals, but I will begin by describing an experiment with the arc, as it raises the question of the origin of these lines in a very direct way. An arc between iron wires passed through hydrogen at about 3 cm. pressure (in this case all the kathode rays would be absorbed quite close to the electrode) for an hour or so, and the gases liberated in the experimenting chamber tested;  $X_3$ , helium, and neon were found. The experiment, using the same wires for terminals, was repeated the next day; the three gases were again found. On the next day, still using the same wires, the arc was passed through oxygen; the  $X_3$  line was still there, though much fainter than before; the helium and neon could not be detected with certainty. The next day, using the same terminals, the arc was again passed through oxygen; not one of the lines could be detected. This looks as if these substances were produced by the arc passing through hydrogen. It was found, however, that, still keeping to the same terminals, on pumping the oxygen carefully out and filling up again with hydrogen, the arc through the hydrogen now did not give even a trace of these lines. On replacing the old iron wires by new ones, and sending the arc through the hydrogen, the lines reappeared. This experiment seems to me to point very clearly to the conclusion that these gases were in the

terminals to begin with, were removed from them by the long-continued sparking, and were not produced *de novo* by the arc.

In the experiments when the discharge was produced in a tube with a Wehnelt kathode, the potential difference between the terminals was only 220 volts, so that the kathode rays in the tube had only a fraction of the energy they had when the discharge was produced by an induction coil;  $X_3$  and helium appeared when the discharge passed through this tube. I did not detect any neon.

The method which gave  $X_3$  and also the other gases, in the greatest abundance, was to bombard metals, or indeed almost any substance, with kathode rays. The tube used for this purpose had a curved kathode, which focused the rays on a table on which the substance to be bombarded was placed. The substance, round the spot struck by the rays, was generally raised to a bright red heat by the bombardment; the bombardment was as a rule continued for five or six hours at a time. I have got the  $X_3$  line, as a rule, accompanied at first by the helium line, and somewhat less frequently by the neon line, when these following substances (which include nearly all I have tried) were bombarded: iron, nickel, oxide of nickel, zinc, copper, various samples of lead, platinum, two meteorites, and a specimen of black mica given me by Sir James Dewar, which was remarkable for the amount of neon it gave off.

The most abundant supply of  $X_3$  came from platinum, and I will describe an experiment with this metal. A piece of platinum foil was bombarded on four days, and the gases produced each day examined. At the end of the first day's bombardment it was found that the line due to  $X_3$  was very strong, those due to helium and neon weaker, but still quite conspicuous. The gases produced the first day were well

washed out of the tube, and the foil bombarded for a second day. The gases formed proved to be much the same as on the first day; there was no appreciable diminution. The examination of the result of the third day's bombardment showed that the  $X_3$  line had diminished considerably, the lines due to helium and neon perceptibly. When the gases produced on the fourth day's bombardment were examined it was found that the  $X_3$  and helium had diminished to such an extent that the lines were barely visible. I could not see the neon line at all. In this case the helium was not eliminated until the fourth day. In general I have found that the helium disappeared long before the  $X_3$  gas. Thus a piece of old lead I bombarded gave off appreciable quantities of helium from the first day's bombardment, very little on the second day, and none that I could detect on the third or subsequent days. The  $X_3$ , on the other hand, came off in considerable quantities up to the end of the experiment, which lasted for six days. I attribute the superior elimination of  $X_3$  in the case of the platinum foil to the fact that during the whole time the bombardment was concentrated on a patch only about 2 mm. in diameter, while the lead melted under the bombardment, so that fresh portions were continually being exposed to the rays. A piece of Kahlbaum's chemically pure lead gave appreciable amounts of  $X_3$  and helium, though not nearly so much as the old lead. I tried some lead which had just been precipitated, but could not detect either  $X_3$  or helium.

In the course of the experiments with old lead I let hydrogen into the experimenting chamber to see if it would increase the amount of  $X_3$ , but could not detect any effect. On one occasion I let in oxygen when nickel was bombarded, also without any appreciable effect. I think these experiments are in favor of the view that

these gases are present in the metal independently of the bombardment, and are liberated by the action of the kathode rays. They are surprisingly firmly held by the metal, and can not, so far as my experience goes, be got rid of by heating. I kept a piece of lead in a quartz tube boiling in a vacuum for three or four hours, until all but a quarter of the lead had boiled away, and examined the gases given off during this process; neither  $X_3$  nor helium could be detected. I then took the quarter that remained and bombarded it, and got appreciable amounts of  $X_3$  and helium. On a second bombardment the  $X_3$  was visible but the helium had disappeared. As an instance of the way these gases can stick to metals even when in solution or chemical combination, I may mention that though, as I have said, platinum foil after long exposure to kathode rays is freed from these gases, yet I got appreciable quantities of  $X_3$  and helium, though no neon from platinum sponge freshly prepared from platinic chloride.

The reason helium is obtained by heating the glass of old Röntgen-ray bulbs is, I think, that after liberation by the kathode rays, the helium either adheres to the surface or is absorbed in a much looser way than before it was liberated. The question as to how these gases get into the metals is a most interesting one; are they absorbed in the process of manufacture? In this connection it is interesting to note that  $X_3$  does not appear to occur to any appreciable extent in the atmosphere. Sometimes when suffering from the difficulty of clearing out these gases I have been goaded into speculating whether they do not represent the partially abortive attempts of ordinary metals to imitate the behavior of radio-active substance; but whereas in these substances the  $\alpha$  particles and the like are emitted with such velocity

that they get clear away from the atom, in ordinary metals they have not sufficient energy to get clear, but cling to the outer parts of the atom, and have to be helped by the kathode rays to escape.

I would like to direct attention to the analogy between the effects just described and an everyday experience with discharge tubes—I mean the difficulty of getting these tubes free from hydrogen when the test is made by a sensitive method like that of the positive rays. Though you may heat the glass of the tube to melting point, may dry the gases by liquid air or cooled charcoal, and free the gases you let into the tube as carefully as you will from hydrogen, you will still get the hydrogen lines by the positive-ray method, even when the bulb has been running several hours a day for nearly a year. The only exception is when oxygen is kept continuously running through the tube, and this, I think, is due, not to lack of liberation of hydrogen, but to the oxygen combining with the small quantity of hydrogen liberated, just as it combines with the mercury vapor and causes the disappearance of the mercury lines. I think this production of hydrogen in the tube is quite analogous to the production of  $X_3$ , of helium, and of neon. I have been greatly assisted in the experiments I have described by Mr. F. W. Aston, Trinity College, and Mr. E. Everett.

J. J. THOMSON

February 8

#### THE SMITHSONIAN AFRICAN EXPEDITION

THE collections made by the Smithsonian African Expedition under the leadership of Col. Theodore Roosevelt, when received, were distributed to the various departments of the National Museum to which they pertained; the birds were sent to the bird department, the large animals to the mammal department, the plants to the botanical department, and so on.

A number of groups of the large mammals have been prepared, and a number of individual specimens mounted for exhibition purposes. Most of the specimens have been placed in the study series, and the duplicates will be distributed by exchange or otherwise.

The groups of large mammals now mounted will shortly be placed on exhibition in the new Museum mammal hall where the larger animals will be exhibited. Those that were on exhibition have been temporarily withdrawn, in order to place them in their proper place in the classification in the hall, which is closed temporarily pending the arrangement of the cases containing the specimens.

It now seems an opportune time to make a final statement relating to the expedition and with this in view the secretary recently communicated with the parties who contributed to the fund, and has thus far received replies from the following that they have no objection to their names being given to the public. In this connection the secretary wishes to state that up to this week Colonel Roosevelt has not known who the contributors were, with the exception of Mr. Carnegie and possibly one or two personal friends.

It has not been the custom of the institution to publish the names of contributors to research work or expeditions conducted under its direction until such enterprise had been completed, and only then when the contributor had no objection to such publication. The contributors include:

Mr. Edward D. Adams, of New York City.  
Hon. Robert Bacon, of Boston, Mass.  
Mr. Cornelius N. Bliss, of New York.  
Mr. James Campbell, of St. Louis, Mo.  
Mr. W. Bayard Cutting, of New York City.  
Mr. Andrew Carnegie, of New York City.  
Mr. Cleveland H. Dodge, of New York City.  
Mr. E. H. Gary, of New York City.  
Mr. John Hays Hammond, of Washington, D. C.  
Col. H. L. Higginson, of Boston, Mass.  
Mr. Hennen Jennings, of Washington, D. C.  
Mr. J. S. Kennedy, of New York.  
Mr. Ralph King, of Cleveland, Ohio.  
Hon. George von L. Meyer, of Washington, D. C.  
Mr. D. O. Mills, of New York.

Hon. T. H. Newberry, of Michigan.  
 Mr. L. L. Nunn, of Provo, Utah.  
 Mr. H. C. Perkins, of Washington, D. C.  
 Mr. George W. Perkins, of New York City.  
 Mr. Henry Phipps, of New York City.  
 Mrs. Whitelaw Reid, of New York City.  
 Hon. Elihu Root, of Washington, D. C.  
 Mr. J. C. Rosengarten, of Philadelphia, Pa.  
 Mr. Jacob H. Schiff, of New York City.  
 Mr. Isaac N. Seligman, of New York City.  
 Mr. O. M. Stafford, of Cleveland, Ohio.  
 Hon. Oscar S. Straus, of New York City.  
 Mr. Isidor Straus, of New York.

From the contributions, the Smithsonian's three fifths share of all the expenses were paid; the other two fifths were paid by Colonel Roosevelt, which covered all his personal expenses and those of his son, and their proportionate two fifths share of the total expenses of the expedition.

The following is the complete list of the collections made by the expedition that have been received by the institution:

	Specimens
Mammals .....	5,013
Birds .....	4,453
Birds' eggs and nests .....	131
Reptiles and batrachians .....	2,322
Fish .....	447
Plants .....	5,153 sheets
Insects .....	3,500
Shells .....	1,500
Miscellaneous invertebrates ..	650
Total .....	23,169

As the result of this expedition, the biological collections now in the National Museum from East Africa are probably the most complete and systematic of any in the world.

#### THE INSTITUTE OF ARTS AND SCIENCES OF COLUMBIA UNIVERSITY

NEW YORK is to have an Institute of Arts and Sciences, which has been organized by Columbia University, to begin operation next fall. The object of the university is to offer its educational advantages to a wider constituency, including professional business men and women, and people of leisure, and to bring the general public into closer relation with its work and purposes. To this end it

has been decided to offer, in the late afternoons and evenings, approximately from October to May, short series of lectures, of the university extension type, on history, literature, art, music, drama, ethics, etc., addresses by distinguished statesmen and educators from home and abroad, illustrated lectures on travel, lecture recitals on forthcoming opera, orchestral programs, the history of music, etc., dramatic readings and recitals, and occasional dramas, authors' readings, concerts and recitals by orchestras, operatic singers, and other artists, and oratorios and chorus concerts by the Columbia University Festival Chorus.

The work of the institute will be distinct from the regular academic work of the university and will not receive academic credit in any way, its aim being mainly to furnish a platform for the free and unbiased discussion of current social and economic questions, and to afford a thorough program for general culture, in other words, to provide a system of adult education and rational recreation of an educational nature for busy people. The university offers at present many miscellaneous public lectures which are provided for by special endowment or by exchange professorships, and at times the attendance has been so large that thousands have been turned away. All these lectures will be incorporated in the program of the institute. While many of these lectures and events will be held in the auditoriums on the university campus it is likely that a part of the program will be offered at a Harlem center and also at a down town center, and, as the work grows, other centers will be established. It is expected that about 300 lectures and entertainments will be offered during the season by the best lecturers and artists.

While no definite program for the first season can be announced now the institute has assurances of the cooperation of the Philharmonic Society Orchestra, the New York Symphony Society Orchestra under Walter Damrosch, the Kneisel quartet, and many other organizations, while well known soloists will probably be included in the list of entertain-

ments. The entire control of the Institute will be in the hands of Professor James C. Egbert, the Director of Extension Teaching, who will be assisted by Milton J. Davies, who was secretary to President George E. Vincent, of the Chautauquan Institution, and later was supervisor of lectures and concerts for the Brooklyn Institute of Arts and Sciences. He leaves the position of educational director of the Brooklyn Central branch of the Y. M. C. A. The fee for membership in the institute is \$10 annually and the first thousand members will not have to pay a registration fee. After that the registration fee of \$5 will have to be paid, once only, however. A membership ticket will admit one person to the day lectures during the entire season, and two to the night lectures. For certain of the more costly events on the program, such as special concerts, membership will be given a reduced rate of admission.

#### SCIENTIFIC NOTES AND NEWS

THE National Academy of Sciences will hold on April 22, 23 and 24, an adjourned meeting to celebrate the semi-centennial anniversary of its foundation. The academy held its first meeting in New York on April 22, 1863. In addition to the American speakers there will be three speakers from Europe, Professor J. C. Kapteyn, of the Astronomical Laboratory of Groningen, Holland, on "The Structure of the Universe"; Professor Arthur Schuster, secretary of the Royal Society of London, on "International Cooperation in Research"; and Professor Theodor Boveri, of Würzburg, on "The Material Basis of Heredity."

THE Oxford University convocation has voted to confer the degree of doctor of science on Dr. Josiah Royce, professor of the history of philosophy at Harvard University, who has been giving a course of lectures at Manchester College, Oxford.

THE University of Calcutta has conferred the degree of doctor of science on Dr. A. R. Forsyth, F.R.S., who has given a course of mathematical lectures at the university.

THE Helmholtz medal of the Berlin Academy of Sciences has been awarded to Professor S. Schwendener, of the Berlin University, for his researches in plant physiology.

At the annual meeting of the Royal Astronomical Society on February 14, the gold medal of the society was presented to M. Henri Delandre, of the Meudon Solar Observatory. Officers were elected as follows: *President*, Major E. H. Hills, C.M.G., F.R.S.; *Vice-presidents*, Sir W. H. M. Christie (late astronomer royal), Dr. F. W. Dyson, Mr. A. R. Hinks and Professor H. F. Newall. Mr. Knobel was reelected as treasurer. Mr. A. S. Eddington and Mr. A. Fowler were elected secretaries, and Sir David Gill was reelected to the office of foreign secretary.

At the anniversary meeting of the Geological Society of London officers for the ensuing year were appointed as follows: *President*, Dr. A. Strahan, F.R.S.; *Vice-presidents*, Professor E. J. Garwood, M.A., Mr. R. D. Oldham, F.R.S. Mr. Clement Reid, F.R.S. and Professor W. W. Watts, F.R.S.; *Secretaries*, Dr. A. Smith Woodward, F.R.S. and Mr. H. H. Thomas; *Foreign Secretary*, Sir Archibald Geikie, President R.S.; *Treasurer*, Mr. Bedford McNeill.

THE Franklin Institute, Philadelphia, acting through its committee on science and the arts, recently awarded the Elliott Cresson gold medal, the highest in the gift of the institute, to the following gentlemen:

Charles Proteus Steinmetz, A.M., Ph.D., of Schenectady, New York, in recognition of successful application of analytical method to the solution of numerous problems of first practical importance in the field of electrical engineering.

Emile Berliner, of Washington, D. C., in recognition of important contributions to telephony and to the science and art of sound-reproduction.

Isham Randolph, D.Eng., of Chicago, Ill., in recognition of distinguished achievement in the field of civil engineering.

John William Strutt, Baron Rayleigh, P.C., J.P., D.C.L., LL.D., F.R.S., Hon.C.E., Sc.D., of Witham, Essex, England, in recognition of extended researches of signal importance in physical science.

Sir William Ramsay, K.C.B., LL.D., D.Sc., M.D., Ph.D., F.R.S., F.C.S., of London, England, in recognition of numerous discoveries of far-reaching importance in the science of chemistry.

Emil Fischer, Ph.D., M.D., D.Sc., F.R.S., of Berlin, Germany, in recognition of numerous contributions of fundamental importance to the science of organic and biological chemistry.

THE annual dinner of the Alumni Association of Stevens Institute of Technology, held on February 14 at the Hotel Astor, took the form of a testimonial to Dr. Humphreys on the tenth anniversary of his inauguration as president of Stevens. The regard of the alumni was evidenced by the presentation of a model of the historic Stevens Castle which was recently purchased by the institute.

DR. JAMES LAW, emeritus professor of veterinary medicine at Cornell University, was seventy-five years old on February 13. In the afternoon Acting President Crane and all the members of the faculty of the Veterinary College called upon Dr. Law at his home to congratulate him.

THE senate on February 20 voted to grant permission to Col. W. C. Gorgas of the Isthmian Canal Commission to enter the service of the Republic of Ecuador for the purpose of cleaning up the port of Guayaquil.

It is announced that the Canadian government will grant Mr. Stefansson the sum of £15,000 towards his expedition into unexplored territory north of the Canadian mainland. Mr. Stefansson will take with him Canadian students with scientific knowledge, and the expedition will be directly under the Canadian Geological Survey. He expects to be absent three winters and four summers.

DR. H. MONMOUTH Smith, since 1902 professor of chemistry at Syracuse University, has accepted a research position in the nutrition laboratory of the Carnegie Institution.

MR. LANCASTER D. BURLING, assistant curator of the division of invertebrate paleontology in the United States National Museum, has resigned to accept the position of invertebrate paleontologist in the Geological Survey of Canada.

MR. ROBERT ANDERSON has resigned as geologist of the United States Geological Survey and will engage in professional work, in partnership with Mr. A. C. Veatch, specializing in the geology of petroleum.

MR. DAVID HOOPER, curator of the Industrial Section of the Indian Museum, Calcutta, has been appointed economic botanist to the Botanical Survey of India.

PROFESSOR BIER, of the University of Berlin, who has been quoted as having spoken favorably of Dr. Friedmann's treatment for tuberculosis, has given out a statement which concludes as follows: "I must therefore publicly protest against the misuse of my name for the recommendation of a remedy of whose effectiveness I have so far no evidence. I hope that this statement may find its way into the foreign press as quickly and as widely as my alleged recommendation of the treatment. It should also relieve me of the burden of constantly answering letters and stating that I have seen as yet no evidence of any unusual curative action of Friedmann's treatment."

A JOINT meeting of the Washington Academy of Sciences and the Philosophical Society of Washington was held on March 1, in the assembly hall of the Cosmos Club, when an address was given by the Right Honorable James Bryce on "The Physical Aspects of Australia and New Zealand."

PROFESSOR EDWIN G. CONKLIN, of Princeton University, will lecture before the Harvey Society at the New York Academy of Medicine on March 8, his subject being, "The Size of Organisms and their Constituent Parts in Relation to Longevity, Senescence and Rejuvenescence."

N. H. DARTON, geologist, Bureau of Mines, gave recently two lectures on applied geology to the advanced geological students at Columbia University. The subjects were "Construction of Structure Maps of Coal Basins" and "Construction of Maps showing Artesian Water Conditions."

PROFESSOR JOHN B. WATSON, of the Johns Hopkins University, is giving at Columbia a course of eight lectures on animal behavior.

The lectures are given on Monday and Tuesday afternoons at four o'clock.

PROFESSOR KARL BEZOLD, of the University of Heidelberg, is lecturing on ancient oriental art at Chicago, Princeton and other universities.

PROFESSOR J. F. KEMP, of Columbia University, lectured on the Catskill Aqueduct of New York and the application of geology to great engineering enterprises, at the Pennsylvania State College on February 25. After the lecture a banquet was tendered Dr. Kemp by the Research Club, consisting of the local members of the Sigma Xi.

THE forty-fourth annual presidential address was given on February 13 by Albert McCalla, Ph.D., before the State Microscopical Society of Illinois at Chicago, the subject being "Microscopic Research as an aid to Industrial Arts and Allied Sciences."

ON February 25 Professor H. H. Turner began a course of three lectures at the Royal Institution on "The Movements of the Stars"; and on Thursday, March 6, Mr. W. B. Hardy delivered the first of two lectures on "Surface Energy." The Friday evening discourse on February 28 was delivered by the Hon. R. J. Strutt on "Active Nitrogen," and on March 7 by Mr. C. T. R. Wilson on "The Photography of the Paths of Particles ejected from Atoms."

DR. PHILIP HANSON HISS, professor of bacteriology in the College of Physicians and Surgeons, Columbia University, the author of important researches on immunity and infectious diseases, died on February 27, aged forty-four years.

CHARLES W. HOOKER, Ph.D., entomologist of the Federal Experiment Station and plant inspector of the Port of Mayaguez, Porto Rico, died on February 12, at the age of thirty, following an attack of appendicitis. Dr. Hooker, who was a graduate of Amherst College in the class of 1906, received his doctor's degree in entomology at the Massachusetts Agricultural College in 1909.

SIR WILLIAM WHITE, F.R.S., the distinguished naval architect, for many years chief

constructor of the British navy, president of the British Association for the Advancement of Science for the next annual meeting, died on February 28, aged sixty-eight years.

#### UNIVERSITY AND EDUCATIONAL NEWS

By the will of John Fritz, the iron master, his residuary estate amounting to about \$150,000 is given to Lehigh University primarily as an endowment fund for the maintenance of the Fritz Engineering and Testing Laboratory. It is also announced that Mr. Charles L. Taylor, of Pittsburgh, has given Lehigh University a gift for a large gymnasium and a stadium.

By the will of the late Mr. C. C. Weld, of Newport, R. I., the Boston Lying-In Hospital receives \$125,000, and the Boston Dispensary \$100,000, while the residuary estate, valued at nearly \$4,000,000, is in case the daughter of the decedent dies without issue, to be divided between the Massachusetts General Hospital and the Massachusetts Institute of Technology.

PLANS for the new electrical laboratory of Harvard University, which is to be built between the Jefferson Physical Laboratory and the Peirce Hall, are nearing completion, and it is expected that actual work of construction will begin early in the spring. The building will cost about \$60,000 and is an anonymous gift to the university.

APPLICATIONS for the Kahn Foundation for the Foreign Travel of American Teachers should be handed to the secretary of the foundation, Sub-station 84, New York City. The next fellows will be selected by the trustees early in May and will begin their travels on July 1, 1913. The reports of the first appointees, Professor Francis Daniels, of Wabash College, and Professor J. H. T. McPherson, of the University of Georgia, are now in the printer's hands. Two fellows are at present abroad: Professor Ivan M. Linforth, of the University of California, is about to leave Germany for the Orient; and Professor William E. Kellicott, of Goucher College, is at present in the British Isles and will shortly

leave for France. The fellowships carry with them stipends of \$3,000 and no obligations other than that of making a year's trip around the world and the rendering of a report thereon to the trustees.

AN anonymous donor has offered to the University of Cambridge £10,000 towards the endowment of a chair of astrophysics.

THE University of Birmingham having received an offer from the Board of Agriculture of a grant-in-aid, to be expended in carrying on a research department in agricultural zoology, has appointed Professor F. W. Gamble, F.R.S., as director of the new department.

DR. WALLACE W. ATWOOD, associate professor of physiography and general geology in the University of Chicago, has been appointed professor of physiography in Harvard University.

#### DISCUSSION AND CORRESPONDENCE

##### CYTOLOGICAL NOMENCLATURE

THE only possible use for a system of nomenclature is to secure accuracy and convenience in its application. So soon as it produces confusion and becomes unwieldy and cumbersome it defeats its purpose. The real reasons for applying a name to an object are to secure its accurate identification and to facilitate description. It is entirely secondary whether this name is descriptive or not. This fact is fully recognized among biologists in establishing the rule of priority, the sole purpose of which is to secure a definite and permanent relation between an object and its name.

Considerations of this sort apparently have no appeal to cytologists, whose nomenclature is accordingly falling into lamentable confusion. This has resulted very largely from an evident desire to make each term descriptive rather than precise. The same object, whose common identity is recognized by every observer, may, in each study, receive a different name because some real, or supposed, characteristic appeals to the describer. The final result of this practise is easily foretold and is even now making itself manifest. The be-

ginner, instead of being able to acquaint himself with the known facts, is obliged to spend a large part of his time in untangling a complicated terminology; and, unless he has the help of some one personally familiar with the varied career of each term employed, is very apt to go astray. Much time and trouble are also expended by the initiated in discussing the relative descriptive values of the names given to the same object.

It should be the purpose of every investigator to make the machinery of his science as simple as possible and to subordinate everything to the main aim of discovery. The reasonable way to accomplish this is to profit by the experiences of workers in other and older fields and to make such applications of general principles as have been found desirable and necessary in actual practise. It is of little moment whether we are endeavoring to discriminate between two organisms or between two structural elements of these organisms—in either case it is necessary for us to designate the contrasted objects by names which apply to them alone. At the same time it very much simplifies the discussion if but a single term is used for each. Systematists have found that the only way to secure this precision is to insist that the first name applied to any kind of organism be its designation, whether descriptive or not. It seems to me that cytologists may well profit by the hard-earned experiences of the taxonomists and avoid the difficulties of an ineffective terminology. Another practise of systematists that is suggestive of simplicity is the use of qualifying prefixes to well-established words where a new term is called for in the discussion of a subgroup. I feel convinced that a recognition by cytologists of these two principles of nomenclature would do much toward reducing the confusion now existing.

There may be some who do not agree with me regarding the subordinate value of the descriptive element in terminology and who would cite the B N A system of anatomists as a support of their view that terms should be descriptive. The conditions confronting the two classes of workers are, however, entirely

different. The anatomists have a very thorough knowledge of their subject so that they may apply descriptive terms with certainty in most cases, and then, again, their major terms are well fixed by long usage and the modifications proposed in the Basle system are in most cases restricted to qualifying terms. Cytologists, on the contrary, have no such familiarity with their subject and there is lacking an agreement regarding the application of even major terms. Undoubtedly the subject of human anatomy forms the best instance of the possibility of the application of descriptive terms, but even here the necessity for their use is definitely denied and provided against by the fourth principle which reads (Barker, B. N. A.):

The terms shall be simply memory signs, and need lay no claim to description or to speculative interpretation.

It thus appears that in two of the oldest branches of biological science, general taxonomy and human anatomy, the necessity for definiteness of application in terms, to the neglect of descriptive value, has manifested itself. It would certainly seem the part of wisdom for cytologists to avoid the difficulties which will inevitably arise through the practise now prevailing in their science by applying well-tried methods in their nomenclature.

C. E. McCLUNG

UNIVERSITY OF PENNSYLVANIA

#### A SUGGESTED CLASSIFICATION OF WRITINGS ON EUGENICS

THE following note is published in response to various inquiries as to a schedule for classifying eugenical writings, for bibliographies, libraries, etc. It lends itself to the decimal system of classification, if desired.

#### *Eugenics*

0. Philosophy and bearings of; compendia, essays; periodicals, societies, institutions (record offices, laboratories, etc.), methods, history, bibliography, biography.

1. Racial anthropology.

2. Genealogy or family history, eugenic and caecogenic families.

3. Heredity, including mental traits, normal and pathological (see "Trait, Book of the Eugenics Record Office," Bulletin No. 6).

4. Differential selection of mates and its social control.

5. Differential fecundity and its social control.

6. Differential survival and its social control.

7. Migration and its social control.

8. Culture of the innate traits; relations to eugenics of education, religion, and work for social and individual welfare.

C. B. DAVENPORT

COLD SPRING HARBOR, L. I.,

February 10, 1913

#### EQUINE PIROPLASMOSIS IN THE CANAL ZONE

TO THE EDITOR OF SCIENCE: I wish to note the occurrence of equine piroplasmosis in the Canal Zone. The parasite closely resembles *Piroplasma caballi* Nuttall, 1910, and differs from *Nuttallia equi* (Laveran) in not displaying "cross forms."

Equine piroplasmosis has, so far as the literature at hand discloses, appeared in only two other localities in America—São Paulo, Brazil, and Venezuela. The infected animal was an American driving horse that had been on the isthmus several years and no doubt became infected from ticks while driven out into Las Sabanas to the Juan Diaz River. The disease is very likely epizootic in the interior of the republic, for native cattlemen speak of a disease of horses there resembling anthrax.

In view of the fact that among animals in the commission corrals, it has been found that horses, from their use on the trails, become infested with ticks, *Dermacentor nitens* chiefly, while the draft mules, from their restricted use on the roads, usually are not infested with ticks; it is interesting to note that piroplasmosis, a tick-transmitted disease, appeared in a tick-infested horse, while murrina, the trypanosomal disease of equines of Panama (fly transmitted) was confined absolutely to draft animals, tick-infested saddle horses

never, under any circumstances, becoming naturally infected.

BOARD OF HEALTH LABORATORY,  
ANCON, CANAL ZONE

#### A REQUEST FROM THE AMERICAN SOCIETY OF NATURALISTS

THE American Society of Naturalists does not possess a complete set of its published "Records." It has no copy of Part IV., Volume II. The secretary wishes to complete at least one set of the "Records" to be deposited with other material at the Wistar Institute.

Several complete sets may be made up if copies of the following can be obtained:  
Volume I, Parts II., III., IV., V., VII., VIII., IX. and XI.

Volume II, Parts I., II., IV., V., VI. and VII.

Members of the society are therefore asked to look through their papers and to write to the secretary if they can supply any of the parts desired.

BRADLEY MOORE DAVIS,  
*Secretary for 1913*

UNIVERSITY OF PENNSYLVANIA,  
PHILADELPHIA, PA.

#### THE FACTS ABOUT THE ACCOUNTS OF LEARNED SOCIETIES

TO THE EDITOR OF SCIENCE: The article by Professor Hart in SCIENCE for January 10 contains errors that need correction. The financial report of the American Academy of Political and Social Science for the year 1910 has been compared with the reports of the other societies for 1911, although the Academy's financial statement for 1911 was printed in May, 1912, eight months before Professor Hart's article appeared.

The apparent discrepancy between membership list and paying members is due to the fact that Professor Hart fails to take into account the 128 life members and 503 subscribers of the Academy represented mainly by libraries and other institutions not eligible to membership.

The statement is made in the article that the expenditure of the Academy, per paying member, was \$6.71 for the year 1910. This calculation is not based on the true figures for membership, and suppresses the fact that \$10,493.00 was received from subscriptions to publications by non-members, from sales of current numbers, from special contributions and from life-membership fees.

The number of pages published during the year 1910 is said to be 1,523 when in fact 2,034 pages were printed. The number of words published in 1910 was 1,176,650 and not 685,000, as stated in the article.

The details are as follows:

37,300 copies of *Annals* issued in 1910.  
1,500 copies of *Annals* reprinted.  
10,700 copies of a Child Labor supplement.  
27,800 copies of four issues of supplements.  
9,500 copies of reprints.

The average cost of printing per 1,000 words was \$16.37, and not \$32.50, but included in this cost are items not directly chargeable to the printing of the *Annals*, as will be seen by the enumeration in the report.

Such are the facts about the American Academy. Professor Hart's statements about the American Historical Association are also incorrect. The proceedings are printed and sent out at government expense, and hence it has no postage bills of this sort in its accounts. The association does not print its own magazine, but has a contract with a publishing house which issues it at a net rate to the members of the association. The receipts for advertising and subscriptions are thus not accounted for in the report of the society, nor does it contain the bills for postage and for clerical help employed by the publishing house. These net costs can not fairly be compared with the gross costs tabulated in the annual report of the American Academy.

SIMON N. PATTEN

IS THE "ACADEMIC COSTUME" WORTH WHILE?

TO THE EDITOR OF SCIENCE: I shall not attempt to answer the above question, raised by Professor Wilder in your issue of January 31. But if the question had been worded "Is

the academic costume worth paying \$35 to \$95 for?" I would quickly answer "No." Considering it desirable to provide myself with a doctor's gown and hood, I purchased the silk and velvet trimming by the yard, and got a dressmaker to make the gown after the pattern of one owned by a friend. As a result I have a first-class gown of the best material, and the cost was about half the regular price of a similar gown ready made.

*Michigan Bird Life, a List of the Bird Species known to Occur in the State Together With an Outline of their Classification and an Account of the Life History of Each Species, with Special Reference to its Relation to Agriculture.* With seventy-five full page plates and one hundred and fifty-two text figures. By WALTER BRADFORD BARROWS, S.B., Professor of Zoology and Physiology and Curator of the General Museum. Special Bulletin of the Department of Zoology and Physiology of the Michigan Agriculture College. Published by the Michigan Agricultural College. 1912. Svo. Pp. xiv + 822, 70 half-tone plates and 152 text figures.

The purpose and general character of the present work are stated by the author to be to provide an authoritative list of the birds of Michigan, with such additional information respecting them as would be useful and of interest not only to the nature lover and general reader, but to students and teachers. In a work originating with and published by a State Agricultural College, it is eminently proper that special attention should be given to the economic status of the species in relation to man's interests, yet it is recognized that each has "a scientific, an esthetic, a human value, which can not be estimated in dollars and cents," and which should forever protect it "from extreme persecution, and above all from final extinction."

An introduction of nearly thirty pages deals with the physiographic and climatic features of the state, the distribution of its

plant and animal life, and especially its bird life with reference to the different areas characterized by special conditions of environment, as prairies, marshes and pine and hardwood forests. The subject "how to study birds" is discussed at some length, and with intelligence and fairness, the conclusion being that field-glass records of rare species by amateurs should not be relied upon as satisfactory evidences of occurrence. Where there is any improbability of a bird being at a given time and place, the record should "rest upon an actual specimen taken at that locality and either preserved for the examination of any one interested or at least examined and identified by a competent authority before being destroyed."

Nearly ten pages are given to the subject of migration, which includes not only comment on the migratory movements of birds in Michigan, but a summary of recent progress in knowledge of bird migration, remarks on the rapidity of flight in birds, and on the disasters known to overtake birds in migration, by which thousands upon thousands lose their lives through adverse weather conditions, so that large areas become nearly depopulated of certain species. Attention is also called to recent changes in the bird life of Michigan through deforestation of large portions of the state, the draining of marshes, etc., and the consequent increase or decrease of certain species.

The main text of the work treats, in systematic sequence, of the 326 species of birds known to occur in the state, with keys to the species and higher groups, a liberal amount of biographical matter, followed by diagnoses in small type. The life histories are especially full, with often somewhat extended discussion of the economic relations of the species to agriculture, for which the author is especially fitted by his twenty-five years of study of the complex relations of birds to insects and crops as a specialist in this field, first under the United States Department of Agriculture and later at Michigan Agricultural College. A "hypothetical list" of 62 species of birds that have been attributed to Michigan by previous

authors, but whose occurrence there is doubtful, is given in an appendix, where the alleged claims of each to a place in the Michigan fauna are set forth. A bibliography of some twenty-five closely printed pages, a glossary of technical terms, a list of contributors to the work, and an index round out the volume, which will take its place among the best of the state ornithological manuals.

J. A. A.

*A School Chemistry.* By F. R. L. WILSON, M.A., Assistant Master at Charterhouse, and G. W. HEDLEY, M.A., Head Science Master, Military and Civil Side Cheltenham College. Oxford, H. Frowde. 1912.

This work has been prepared to supply a demand for a shorter course than the author's "Elementary Chemistry." One who has completed the work in a satisfactory manner is prepared to take the matriculation examinations for a number of English universities. The directions for work are very full and the selection and arrangement of experiments are excellent. Wherever possible the experiments are carried out quantitatively and questions and problems are introduced at the end of each chapter. The use of this book by a student should develop his powers of observation and scientific method of reasoning and give him a good insight into the fundamental principles of chemistry.

J. E. G.

*Practical Chemistry for Engineering Students.* By A. J. HALE, B.Sc. (London), with an introductory note by Professor R. MELDOLA. London, Longmans, Green & Co. 1912. \$1.00 net.

In the introductory note attention is called to the fact that while chemistry is recognized as necessary for engineering students, owing to the short time at their disposal for this subject and the lack of appreciation of its value by the students themselves, the course in this subject must be so arranged as to give as much as possible in a short time. In order to get some training in quantitative analysis 'they must know some general chemistry and

qualitative analysis. Although this book is intended primarily for engineering students it is possible, by the selection of certain designated experiments, to use it in connection with a course in the chemistry of building materials. The experiments in general chemistry are well selected to bring out the general principles of the subject, and the experiments are arranged in such a manner as will bring out the quantitative relations whenever possible. This is followed by a short course on qualitative analysis and work in quantitative analysis, the latter being selected to give practise in the preparation of standard solutions, gravimetric and volumetric determinations and methods of analysis of materials of special importance for the engineer, such as water analysis, determinations of the value of fuel, furnace gases, analysis of cements and alloys. While the general method here used would be approved by most chemists, the necessarily limited number of quantitative methods which can be given would no doubt lead to a wide divergence of opinion as to the ones best suited for the purpose.

J. E. G.

*Review Questions and Problems in Chemistry.*

By M. S. H. UNGER, A.M., Head Master, St. John's School, Manlius, N. Y. Ginn & Co. 50 cents.

An excellent manual for use in reviewing classes or formulating examination questions in preparatory school work, covering as it does all the material necessary for college entrance or college board examinations.

##### THE TEMPERATURE COEFFICIENT OF THE COAGULATION CAUSED BY ULTRAVIOLET LIGHT

It has been pointed out in a previous paper<sup>1</sup> that certain proteins coagulate when exposed to ultraviolet light. In order to learn something about the nature of this reaction it seemed desirable to investigate its temperature coefficient. As photochemical reactions in general are nearly independent of tempera-

<sup>1</sup> SCIENCE, N. S., 37: 24-25, 1913.

ture, it seemed possible that the speed of the coagulation might not be greatly affected by temperature.

In order to test this matter, crystallized egg albumin was prepared by the method of Hopkins and Pinkus. The albumin was recrystallized seven times; the ammonium sulfate was not dialyzed out. A 5 per cent. solution of this albumin was placed in quartz test tubes and exposed to the light from a quartz mercury vapor lamp. The temperature was controlled by keeping the quartz test tubes in water baths automatically maintained at various temperatures and so arranged as to give the tubes equal illumination. The amount of coagulation was estimated by measuring the amount of deposit in the test tubes after centrifuging in sedimentation tubes. The result of these experiments indicated that the temperature coefficient equals or exceeds two.

Of especial interest is the behavior of the tubes which were kept at 0° C. These tubes were still clear after being exposed to the light for 35 hours, while those exposed at higher temperatures contained coagulum. If the tubes which had been exposed at 0° C. were warmed a few degrees their contents began to coagulate. If they were put back into the ice water as soon as the coagulum began to appear the reaction was reversed and the tubes cleared up. This result could be obtained only by cooling the tubes to 0° C. as soon as the coagulum began to appear.

We are dealing here with at least two reactions, first, the change produced by the light, and, second, the production of a visible coagulum.<sup>2</sup> Only the latter has a temperature coefficient as high as two. To demonstrate this it is only necessary to expose tubes at various temperatures for a few hours, turn off the light, remove the tubes from the bath at 0° C. and place them in a warm bath. Although the tubes are perfectly clear when removed from

the ice water, a coagulum appears as soon as they begin to warm up. The amount of this coagulum is about the same as if the tubes had been kept in the warm bath during the entire period of exposure to the light. It is therefore evident that the action of the light is about the same at 0° C. as at the higher temperatures. We are apparently justified in concluding that the light produces a substance which promotes coagulation and produces it about as rapidly at the lower temperature as at the higher, but that this substance is unable at 0° C. to bring about any visible coagulation, at least during the time of this experiment. Evidently the temperature coefficient of the light reaction is very low in this case, as is the rule in light reactions. The method of the experiment yielded only approximate results, since the tubes which were kept at 0° C. and which remained clear during the exposure allowed a better penetration of light than those maintained at higher temperatures in which coagulum formed. The highest temperature was only 50° C.

These experiments allow an interpretation of the results of Blackman and Matthei<sup>3</sup> according to whom the process of photosynthesis has a temperature coefficient as high as two. It is of course highly improbable that a photochemical reaction has a temperature coefficient which is so high. It seems much more probable that in photosynthesis, as in the coagulation above described, light acts almost independent of temperature in producing a substance which then undergoes a reaction with other substances, and that it is this latter reaction which has the high temperature coefficient.

The time-temperature curve of the coagulation of proteins by heat has been worked out with great care by Chick and Martin.<sup>4</sup>

<sup>2</sup> "Experimental Researches on Vegetable Assimilation and Respiration. III. On the Effect of Temperature on Carbon-dioxide Assimilation," *Phil. Trans. Roy. Soc. of London*, B, 197: 47-105, 1904.

<sup>3</sup> "On the Heat Coagulations of Proteins," *Journal of Physiology*, 40: 404, 1910; *ibid.*, 43: 1, 1911.

<sup>2</sup> In the presence of certain salts some proteins in solution may be denatured by heat, but no visible coagulum forms until the salts are dialyzed out. Whether this has any relation to the phenomenon here described can not be discussed at present.

In order to determine whether the character of this curve is altered by exposing the protein to ultraviolet light experiments were made with egg albumin which had been freed from ammonium sulfate by dialyzing for a long time against tap water. The albumin was exposed at 0° C.: samples were then placed in tubes and heated to various temperatures in a water bath. The tubes were centrifuged and the volume of coagulum estimated. The method gave only approximate results. However, they were consistent, and the differences in the amount of coagulum obtained under the various conditions were so great that it is evident that the temperature-time curve for coagulation, by heat, of egg albumin which has been exposed to the light, is of the same general form as the one given by Chick and Martin. But the curve lies at all points from 10° to 15° C. below the one given by them.

The chief result of these experiments is that two reactions are involved in the coagulation of proteins by light: the chemical change caused by the light, and the production of a visible coagulum. The light reaction has a very low temperature coefficient, while the reaction producing the visible coagulum has a much higher temperature coefficient. It is probable that similar relations exist in other biochemical and physiological processes which result from the action of light.

HARVARD UNIVERSITY

#### THE BOTANICAL SOCIETY OF AMERICA

THE annual meeting of the Botanical Society of America was held in the Chemical Building of Western Reserve University, Cleveland, Ohio, December 31 to January 2, 1913.

The following officers were elected for the ensuing year:

*President*—D. H. Campbell, Leland Stanford University.

*Vice-president*—M. A. Howe, New York Botanical Garden.

*Treasurer*—Arthur Hollick, New York Botanical Garden.

*Councilor*—George F. Atkinson, Cornell University.

These with R. A. Harper and William Trelease, councilors, and George T. Moore, secretary, constitute the council for 1913.

The following botanists were elected to associate membership: Robert F. Griggs, Ohio State University; Alfred P. Dachnowski, Ohio State University; Warner Jackson Morse, Maine Experiment Station; L. Lancelot Burlingame, Leland Stanford University; John J. Thornber, University of Arizona; James Theophilus Barrett, University of Illinois; Arlow Burdette Stout, New York Botanical Garden; Ezra Brainerd, Middlebury, Vt.; Norman Taylor, curator, Brooklyn Botanic Garden; William Dana Hoyt, fellow by courtesy, Johns Hopkins University; Edward M. Gilbert, University of Wisconsin; Lester Whyland Sharp, Alma, Michigan; William Skinner Cooper, Carmel, California.

A symposium on "Permeability and Osmotic Pressure" was held January 1, participated in by Professors Jacques Loeb, Harry C. Jones, W. J. V. Osterhout and Burton E. Livingston. The papers will be printed in the *Plant World*.

The address of retiring President W. G. Farlow, on "The Change from the Old to the New Botany in the United States,"<sup>1</sup> was delivered at the dinner for all botanists, on the evening of January 1.

Amendments to the constitution, making it possible for all those actively interested in botanical work to become eligible for membership and providing for "fellows," were adopted. The dues for 1913 were made \$1.00. Active steps for the publication of a botanical journal by the society were taken.

*First Generation Hybrids between *Oenothera lamarckiana* and *O. cruciata**: GEORGE H. SHULL, Carnegie Institution.

*Constant Variants of *Capsella**: HENRI HUS, University of Michigan.

Pedigree cultures from the original individual proved the existence of constant forms, not previously reported. Some of these apparently are not identical with the biotypes previously described by Shull. Emphasis is laid on the importance of the study of seedling stages, since, for purposes of identification, climax leaves may be relied upon under certain conditions only.

<sup>1</sup> SCIENCE, January 17, 1913.

*The Problem of the Origin of Ænothera Lamarckiana De Vries*: B. M. DAVIS, University of Pennsylvania.

The identification of Lamarck's evening primrose, *Ænothera Lamarckiana* Seringe 1828 (*O. grandiflora* Lamarck 1798), as a form of *Ænothera grandiflora* Solander 1789,<sup>2</sup> has materially changed the situation with respect to the origin of the plant which has been the subject of such extensive experimentation by Professor De Vries. *Ænothera Lamarckiana* Seringe becomes a synonym of *O. grandiflora* Solander and the plant of De Vries's cultures is left without a name or at least without the authority of Seringe. I have proposed in the paper cited above that the name *Lamarckiana* be kept for De Vries's plant and that the name be written *Ænothera Lamarckiana* De Vries. The retention of the old name is justified by the fact that the *Lamarckiana* of De Vries's cultures is not known as a native species in any part of the world and there is good reason for believing that the plant has come down to us as a hybrid and a product of a long period of cultivation. To change the name of this plant made famous by the studies of De Vries would carry endless confusion through the literature of experimental morphology.

*Ænothera Lamarckiana* De Vries first appeared on the market when introduced by the firm of Carter and Company, seedsmen in London, about 1860. There is evidence from a sheet in the Gray Herbarium<sup>3</sup> that this plant underwent certain modifications during the twenty-five years that elapsed before De Vries began his studies upon *Lamarckiana*. The problem of the origin of *Ænothera Lamarckiana* then centers on the history and composition of the cultures of Carter and Company.

Carter and Company state that they received their seed unnamed from Texas. If this is correct we have reason to hope that thorough exploration in the south and west may bring to light large-flowered ænotheras from which *Lamarckiana* might have been derived either directly or indirectly as a hybrid. American botanists have then the problem of the discovery and isolation by culture of any large-flowered ænotheras in the south and west which might have had a direct relationship to *Lamarckiana* or which might have been

one of the parents of a possible cross. The rediscovery of *Ænothera grandiflora* Solander in Alabama was a good beginning in this search, but the search should be pushed further. There is thus a tangible problem of whether or not such forms are or ever were present as native American species. If they were present in Texas in 1860 they may surely be expected there to-day.

The fact that large-flowered ænotheras were established in England as early as 1806 in localities (as the sand hills of Lancashire) which are at present occupied by extensive growths of *Lamarckiana* suggests the possibility that *Lamarckiana* was in England before 1860 and that the cultures of Carter and Company may have come not from Texas but from some part of England, and that their association with a Texan source may have been some mistake on the part of the seedsmen. English botanists have the problem of the history of such *Ænothera* floras as that of the Lancashire sand hills, and collections should be searched with great thoroughness for herbarium sheets that may be of assistance in tracing its development.

With Lamarck's plant, grown in Paris about 1796, identified as a form of *Ænothera grandiflora* Solander there has developed a much clearer situation than formerly when attempts were made to place the time of the introduction into Europe of *O. Lamarckiana* De Vries at various dates previous to 1778, the year when *O. grandiflora* Solander was introduced at Kew. There is then on historical grounds no evidence why *Lamarckiana* De Vries might not have arisen in England after 1778 as a hybrid between forms of *grandiflora* and forms of *biennis*. This is the working hypothesis which is receiving strong support from my experimental studies with hybrids between strains of *biennis* and *grandiflora*.

An exhibit of hybrids between *Ænothera biennis* and *O. grandiflora* that resemble *O. Lamarckiana* De Vries was then discussed.

*The Experimental Demonstration of the Validity of the Biological Doctrine of Recapitulation*: E. C. JEFFREY, Harvard University.

*The Plant Formations of the Nebraska Sandhills*: R. J. POOL, University of Nebraska.

The sandhills of Nebraska cover an area of approximately 20,000 square miles, which lies to the north and west of the central portion of the state. The soil of the upland is a straw-colored sand mostly of Tertiary origin. This sand has been blown into innumerable dunes which cover the

<sup>2</sup> See Davis, *Bull. Tor. Bot. Club*, November, 1912.

<sup>3</sup> See Davis, *Amer. Nat.*, XLVI, p. 417, 1912.

underlying rocks of the Arikaree formation with a loose porous soil varying in depth from a few feet to over 150 feet. Wind action is still a pronounced factor in shaping the topography of the uplands, although the region as a whole is practically stabilized by invading vegetation. The influence of wind is reflected most forcibly at present in the regions of active "blow-outs" and "sand-draws."

The greater part of the upland in this great dune region is effectively held against wind erosion by the Bunch-grass Association, a sub-division of the Prairie Grass Formation. Another conspicuous association of the upland is the Blow-out Association. The valleys are characterized by less xerophilous association which in the main are members of the Prairie Grass Formation to the east. The Short Grass Formation has pushed in from the west in a number of places and has occupied especially the hard land in some of the valleys. Forest formations are found along streams and spring branches that are related to the central hardwoods region and to the Rocky Mountain forest region. The streams, wet valleys and numerous lakes reveal the presence of a number of marsh and aquatic associations which are in the main similar to such associations found farther eastward in the Prairie Grass Formation.

*The International Phytogeographic Excursion of 1911 and 1913:* H. C. COWLES, University of Chicago.

In August, 1911, there was held in the British Isles under the auspices of the British Vegetation Committee the first International Phytogeographic Excursion. A dozen phytogeographers from six different countries were conducted to the places in England, Scotland and Ireland where the natural vegetation is of greatest interest. In all the places visited there were competent British guides, who were very familiar with the vegetational features to be considered. The guiding spirit of the excursion was Dr. A. G. Tansley, of Cambridge, who accompanied the party throughout the tour, and attended to numberless details.

Among the many valuable features of the British excursion were (1) the opportunity of getting intimately acquainted in a short time with the most important features of the British vegetation; (2) the opportunity to know in intimate fashion the British botanists who accompanied the party and who were met from place to place, and to know with special intimacy the foreign colleagues with whom we were associated closely every day

for a month; (3) the opportunity to discuss the problems of vegetation as we met them together in the field, and thus without misunderstanding one another and with the certainty that we were talking about the same things.

It was the unanimous opinion of those who participated in the British excursion that the benefits to all were so considerable that similar excursions should be made a permanent feature of International Phytogeography, and at frequent intervals. The second excursion has been definitely announced for the United States in August and September, 1913, and it has been suggested that a third excursion be held on the continent of Europe, immediately after the conclusion of the London Botanical Congress in 1915. It is hoped that American botanists, and especially those interested in the advance of ecology and plant geography, will cooperate in every way possible to make the excursion of 1913 a great success.

*Prairie Openings in a Forest Region:* B. SHIMEK, Iowa State University.

A prairie opening on the exposed terminus of a ridge near Iowa City, Iowa, has retained its original prairie flora through all the changes incident to the clearing of much of the surrounding country and the building of an electric railway which cuts a part of the ridge.

The distinction between the flora of this area and an adjoining timbered tract is sharply brought out by comparative lists of the plants. The plants of the latter area are broad-leaved, and the leaves present a distinct dorsi-ventral structure, while those of the prairie are narrow-leaved, and the leaves are often more nearly erect or ascending.

A comparison of evaporation and transpiration on the two areas shows that evaporation is much greater on the open surface, but that transpiration may be less.

An artificial opening, created by a road-clearing through the original forest near Homestead, Iowa, more than fifty years ago, is similarly discussed with reference to its flora. The greater part of the area is somewhat sandy, and the road-strip, which is about fifty feet wide, extends almost due north and south through about a mile of forest.

This roadway has been kept clear of larger brush and small trees which occasionally spring up, and as a result a very characteristic prairie flora has taken possession of most of the roadside.

Both areas are discussed with reference to their bearing on the question of the causes of the treelessness of the prairies, and the fact is emphasized

that prairie fires especially could not have been the cause.

*Vegetation Features of the Columbus Quadrangle:*

A. DACHNOWSKI and F. B. H. BROWN.

*The Genus Helianthus in Southern Michigan:* S. ALEXANDER.

This paper involves the recognition of a large number of new forms. An attempt is made to classify sunflowers on the basis of their underground systems and of their venation.

*The Regulatory Formation of Tannase in Aspergillus niger and Penicillium sp.:* LEWIS KNUDSON, Cornell University.

*Aspergillus niger*, *Penicillium rugulosum* and *Penicillium* sp., can ferment tannic (gallo-tannic) acid, gallic acid resulting. Employing the two organisms *Aspergillus niger* and *Penicillium* sp., the writer made experiments in which a modified Czapek's solution was employed as the nutrient medium. When the source of carbon is tannic acid, gallic acid or cane sugar supplemented by tannic or gallic acids at certain concentrations, these organisms form the enzyme tannase. In the absence of tannic or gallic acids no tannase is formed. In these experiments the effect of each of fourteen other organic compounds was tested, but none could stimulate the formation of the tannase. The gallic acid is not as efficient as the tannic acid in stimulating to formation by these organisms the enzyme tannase.

In certain experiments the influence of concentration of tannic acid on the quantity of the tannase produced was determined. The source of carbon was 10 per cent. sugar supplemented by tannic acid in variable quantities. It was found that the greater the concentration of tannic acid present the greater is the quantity of the enzyme tannase produced. The greatest quantity of enzyme is produced when tannic acid is the sole source of carbon. In other experiments the source of carbon was 2 per cent. tannic acid, and variable quantities of cane sugar employed. It was found that the higher the concentration of cane sugar the less is the quantity of tannase produced.

*The Relation of Ventilation to the Respiration of Fruits:* GEORGE R. HILL, JR., Missouri Botanical Garden.

A study was made of the respiration and other metabolic phenomena of green and well-ripened fruits which had been placed in nitrogen, hydrogen air and carbon dioxide. Cherries, blackberries, green, market-ripe and very ripe peaches, ripe red Astrachan apples and Concord and Catawba

grapes were used. Particular attention was given to an investigation of the common cold storage injury to peaches, "ice-scald," and the results point quite definitely to a close relationship between it and anaerobic respiration. The keeping qualities of the fruits in storage in the gases named, and the relation of these to ventilation, was also considered. The experiments were run in triplicate and the temperature was kept constant by an apparatus devised especially for the purpose.

*Conditions Affecting the Development of Lycopin in the Tomato:* B. M. DUGGAR, Missouri Botanical Garden.

Willstätter and Escher have shown that the red pigment of the tomato (lycopin, solanorubin) and carotin (derived from the carrot) are isomeric compounds, readily distinguishable by their physical properties. In the ripening tomato both lycopin and carotin occur. An experimental study of the effects of various conditions upon ripening demonstrates that while carotin is developed under conditions of growth differing widely, lycopin is formed only within a limited range of metabolic activity. Temperature and oxygen supply are two of the factors indirectly limiting lycopin development. In yellow varieties of the tomato "carotin" only is found, and in red varieties lycopin formation is precluded by high temperature, yellow fruits resulting. Irreversible effects are not produced by heat. Red tomatoes seem to contain a factor for redness superimposed upon the factor or factors for yellow, and this conclusion is borne out by breeding experiments.

*A Chemical and Physiological Study of After-ripening of the Rosaceæ:* SOPHIA ECKERSON.

The Hawthorn is one of the few seeds where there is known to be a dormancy of the embryo. A period of "after-ripening" is necessary before germination is possible. Food is stored in the embryo as a fatty oil. Neither starch nor sugar is present. The reaction of the cotyledons is acid, but the hypocotyl is slightly basic. The water-absorbing power of the hypocotyl is less than 25 per cent. of the wet weight.

There is a series of metabolic changes in the embryo during the period of after-ripening. The initial change seems to be an increased acidity. Correlated with this is an increased water-holding power, and an increase in the activity of catalase and peroxidase. Near the end of the period of after-ripening there is a sudden greater increase in the acidity, and in the water content. All of

these increase until the hypocotyl is 3-5 cm. long. At this time the fats decrease and sugar appears.

The after-ripening period can be shortened greatly by treating the embryos with dilute solutions of HCl, butyric and acetic acids. The water-holding power, the acidity and the activity of peroxidase increase much more rapidly than in the untreated embryos.

*The Use of Celloidin Membranes for Demonstration of Osmosis:* G. M. SMITH, University of Wisconsin.

The membranes were prepared by pouring a 10 per cent. solution of celloidin on a dish of clean mercury and, after allowing the celloidin to dry sufficiently to be lifted, it was placed over the end of a thistle tube, tied down and allowed to harden. Two membranes were made, one over the other; the double membranes proving themselves ten times as strong as the single ones. The tensile strength of the membrane was found by setting up the osmometer and pouring in mercury and noting the height of the column, when the rupture of the membrane occurred. The double membranes stand over three atmospheres pressure without breaking.

The membranes were rendered semipermeable by putting a M/20 potassium ferrocyanide solution inside of the osmometer and immersing the apparatus in a M/20 copper sulphate solution. A good membrane is formed within the celloidin in three days. When a celloidin membrane separates water and a 3M cane sugar solution the liquid in the osmometer will rise about seven feet in three days and then sink; but when the celloidin membrane contains a copper ferrocyanide precipitate the liquid will rise about twenty-five feet in ten days and then slowly sink.

*Studies of Osmotic Pressure:* M. A. BRANNON, University of Chicago.

This report is based upon studies made in the plant physiological laboratories at the University of Chicago. The work extended over a period of ten months. The measurements of osmotic pressure were made by cryoscopic methods, the Beckmann apparatus being employed to determine the freezing points of the solutions used.

Three different kinds of potatoes were chosen. They were placed in controlled conditions so that only one limiting factor, heat, was involved in the experiments. One collection of potatoes was placed in an icebox where a temperature of 2° C. was maintained and one collection was kept at a temperature of 25° C.

At the beginning of the experiments the osmotic pressure of the different potatoes was about 7 atmospheres. After ten months the icebox potatoes had developed a maximum osmotic pressure of 13 atmospheres. The lower temperature favored metabolic activities resulting in the liberation of an acid, a catalyte and the fermentation of foods, stored in the form of starch and hemicellulose. The change from colloids to crystalloids was accompanied by the rise in osmotic pressure noted.

The fermentation of the hemicellulose was indicated microscopically by the great reduction in the thickness in the cell walls of the potato tissue affected, and also by the great increase in the brittleness of the potato tissues involved.

These studies are suggestive of the changes taking place in the after ripening of seeds, tubers and bulbs, and has a definite relation to several economic and scientific problems.

*Protoplasmic Contractions Resembling Plasmolysis which are caused by Pure Distilled Water:* W. J. V. OSTERHOUT, Harvard University.

True plasmolysis can be produced only by solutions which are hypertonic, but appearances almost or quite undistinguishable from it may be brought about by hypotonic solutions. Some light is thrown on the nature of this result by a study of certain cases in which it is caused by pure distilled water. Material for such study is afforded by marine plants.

The root tips of the eel grass (*Zostera marina*) are well adapted to this purpose. The root tips were carefully removed from the sand in which they were growing and immediately placed in sea water.

The application of distilled water causes a contraction of the protoplasm which often closely resembles the true plasmolysis produced by hypertonic sea water (which has been concentrated by evaporation) or by hypertonic sugar solutions. The mode and the degree of contraction vary somewhat, but in general the variations in true plasmolysis are of the same sort, as in what may be conveniently called the false plasmolysis. We may use the term false plasmolysis to designate not only the contraction produced by distilled water, but also that which is caused by certain hypotonic solutions.

*The Effect of Anesthetics on Permeability:* W. J. V. OSTERHOUT, Harvard University.

Experiments were performed to test the elec-

trical conductivity of living tissues in various solutions. The results show conclusively that a great variety of ions readily penetrate living cells and that this penetration may be markedly hindered or accelerated by the addition of various substances to the solution. The addition of anesthetics, such as ether and chloroform, has a retarding effect on the penetration. It would seem, therefore, that these substances should retard all physiological processes which depend on the transport of ions through living tissues.

*Plants which Require Sodium:* W. J. V. OSTERHOUT, Harvard University.

It is generally believed that plants do not require sodium, although it is indispensable for animals. Our increasing knowledge of the biological rôle of salts makes it clear that such a distinction between plants and animals is of fundamental importance, provided it be true in all cases. But if exceptions to it be found its significance largely disappears. I have therefore undertaken to ascertain whether or not there are plants which require sodium and have begun by examining some marine plants. The results are as follows:

The marine plants studied require sodium; its replacement in sea water by  $\text{NH}_4$ , Ca, Mg, K, Ba, Sr, Cs, Rb or Li is very injurious.

The best substitutes for Na are the other salts of the sea water, Mg, Ca and K.

The diversity in behavior of various species toward the salts which were used to replace the sodium shows that each of these salts has a specific rôle in life processes.

*Studies of the Wild Oat:* W. M. ATWOOD, University of Chicago.

*Avena fatua* (L.) has become a pest agriculturally in the small grain regions of the north and west. In studying its germinative qualities we have found it to possess high vitality. This differs from the deductions which might be drawn from the results of other workers who have tested the seed after periods of burial in the ground.

*Avena fatua* germinates poorly after harvest, but the per cent. of germination increases steadily up to the succeeding spring and summer.

The early delay of germination appears to be due neither to the chemical condition of the embryo nor to coat obstructions to water entry. Oxygen seems to be the limiting factor to germination which can be forced by breaking the coats or increasing the oxygen pressure.

Investigations are now under way to determine whether the so-called "after-ripening" of the

seed is due to alterations in the oxygen demands of the embryo or to increased permeability of the coat to oxygen.

*Toxicity of Smoke:* LEE J. KNIGHT and WILLIAM CROCKER, University of Chicago.

Molisch has found tobacco smoke extremely toxic to plants of various kinds ranging from bacteria to the highest angiosperms. He finds this toxicity is not due to volatilized nicotine, for cellulose paper smoke is as toxic, but believes it is due to CO.

In the burning of organic compounds the destructive distillation carbon-bearing gases,  $\text{CO}$ ,  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{H}_4$  and  $\text{CH}_4$  are not generally completely burned and may be the source of injury in the smoke. Exact experiments on the delicate sweet-pea seedling, Early Cromer, shows that smoke from cigarettes, cigars and cellulose paper cigarettes does not contain sufficient  $\text{CO}$ ,  $\text{C}_2\text{H}_2$  or  $\text{CH}_4$  to determine 1/200 the toxicity of the smoke. This leaves  $\text{C}_2\text{H}_4$ , which we have already shown as extremely toxic to plants, as the substance probably determining the toxicity. The injury from smoke in our cities has been attributed to  $\text{SO}_2$  and  $\text{SO}_3$ , so far as gases are concerned. The possible effect of the dry distillation of carbon-bearing gases has been entirely neglected. They are produced in small amounts in the burning of coal. This coupled with their extreme toxicity (especially ethylene) makes them probable factors in the smoke question.

*A Delicate Test Seedling:* WILLIAM CROCKER, LEE J. KNIGHT and R. CATLIN ROSE, University of Chicago.

We have already published on the characteristic response that the etiolate of sweet pea seedlings give to ethylene. It has been termed a triple response, since it is marked by reduction in rate of elongation, increased growth in diameter and diageotropism. We have since studied the effect of more than fifty gases and vapors upon the seedling, including the paint solvents, the possible impurities of laboratory air, the main constituents of illuminating gas and the principal distillation products of coal tar. The seedlings are apparently reliable and extremely delicate in testing for ethylene—2,000 to 5,000 times as delicate as gas analysis methods. While a few other gases and vapors, carbon monoxide, acetylene, benzene, toluene, xylene, thiophene, cumene and others give the triple response they must be present in such quantities as to be easily detected by other means or they are excluded through impossibility of their

presence in the gas studied. We believe the response of this seedling furnishes a very delicate means of detecting the presence of "heavy hydrocarbons" in laboratory and greenhouse air, in smoke of all sorts and in furnace gases.

*The Heat of Absorption of Water in Wood:*

FREDERICK DUNLAP, U. S. Department of Agriculture.

The heat evolved when water wets dry wood has been studied with the Bunsen ice calorimeter. Oven-dry wood was used; this was sealed in glass to prevent premature wetting. The wood and water were both cooled to 0° C. and brought together at this temperature and the heat evolved was measured. This is large enough to raise the dry wood entering into the reaction from 0° to about 50° C. Under the assumption that the specific heat of wet wood is the sum of the specific heats of the wood and water present in wet wood, its temperature would be raised to about 30° C.

The substance of wood as distinct from the cavities of the cell lumina is saturated when it has imbibed about 25 per cent. of its weight of water. The first per cent. imbibed produces a relatively great evolution of heat; the twenty-fifth, a relatively small evolution of heat, the curve connecting the two being convex upward.

Wood is hygroscopic and its moisture content varies with that of the atmosphere about it. The "working" of wood is due to changes of volume of its substance with changing moisture content. Measures to prevent this "working" aim either to remove the wood from the action of the atmosphere or to render it insensitive to changes in the atmosphere by destroying its hygroscopicity, at least in part. Experiments whose aim it is to destroy the hygroscopicity of wood are now in progress in the Forest Products Laboratory, and this method will be used in studying the changes produced.

*Artificial Parthenogenesis in Fucus:* J. B. OVERTON, University of Wisconsin.

The occurrence of natural parthenogenesis has been reported for several species among the Phaeophyceæ. It is evident that this group shows a strong tendency to develop without fertilization and that natural parthenogenesis may play an important part in the life history of several species. Although Thuret mentions that unfertilized eggs of *Fucus* kept for several days become pear-shaped and that a cellulose wall is sometimes present, none of the *Fucaceæ* have been described as being able to develop without fertilization.

While working at the Marine Biological Laboratory the past summer, the well-known experimental methods of certain animal physiologists, whereby unfertilized eggs of certain animals have been made to develop under the influence of artificial physical and chemical stimuli, were applied to *Fucus* eggs. In plants used for experiment care was taken to prevent contamination by sperms. That female plants may be made perfectly sterile by washing in fresh water is shown by the fact that none of the eggs of such sterilized plants ever developed in the numerous controls which were run in connection with the experiments. In experimenting, the eggs used at any one time were divided into three lots. One lot was used as a control, another was fertilized and the third was placed for one third minute in a mixture of 50 c.c. of sea-water + 3 c.c. 0.1 *m* acetic or butyric acid. A large number of the eggs treated with these solutions become invested with a cell-wall in about 10 minutes. This wall is exactly similar to the one formed about normally fertilized eggs. The wall is readily seen by plasmolyzing the eggs. After the formation of the membranes, if the eggs are transferred to hypertonic sea-water for 30 minutes and then are brought back into normal sea-water, development continues. Such eggs become pear-shaped, showing a rhizoidal papilla, and by next day have cleaved. If the cultures are kept properly aerated, sporplings of about 25 cells develop in the laboratory, resembling in every respect those grown from fertilized eggs.

It would appear that the action of the acid in inducing cell-wall formation about unfertilized *Fucus* eggs is similar to the action which calls forth membrane formation in the animal egg. Considerable evidence exists indicating that the essential condition for the formation of the fertilization membrane in such eggs is an increased permeability of the plasma membrane to substances which harden in contact with sea-water. That the first effect of the sperm upon *Fucus* eggs is to cause cell-wall formation is apparent from the observations of several investigators.

No attempt was made to grow the sporplings under natural conditions. The methods used by Hoyt and Lewis are suggestive and it seems probable that the sporplings produced parthenogenetically could be grown to sexual maturity, so that the nuclear behavior during oogenesis and spermatogenesis might be investigated.

*The Periodicity of Algæ:* E. N. TRANSEAU, Illinois State Normal School.

The preliminary observations on algal periodicity given in this paper are based upon a study of eighteen hundred collections made at many stations in eastern Illinois during the past five years. The general richness of the waters of this region may be judged by the fact that the genus *Cedogonium* is represented by more than forty-five species and *Spirogyra* by thirty-five. Field observations indicate that sexual reproduction in nature is induced by a more definite combination of environmental factors than asexual, since the former is usually restricted to a short period of time, while the latter may occur at intervals or continuously throughout the vegetative period of the algæ.

On the basis of the time of greatest frequency, duration of the vegetative cycle and time of reproduction, algæ may be classified as follows:

1. *Spring Annuals*.—Forms whose vegetative period begins in late autumn, reaches its maximum in April and May and is followed by a decline in June. Fruiting occurs in April, May and June.

2. *Summer Annuals*.—Vegetative period begins in spring, culminates in July and August, followed by decline in autumn. Fruiting occurs in July, August and September.

3. *Autumn Annuals*.—Vegetative period begins in spring and early summer, culminates in autumn, decline comes with the beginning of freezing temperatures. Fruiting occurs in October and November.

4. *Winter Annuals*.—Vegetative period begins in autumn, continues through the winter under the ice and culminates in early spring. Fruiting occurs from November to April.

5. *Ephemerals*.—Forms having a vegetative period of a few weeks or days. Fruiting occurs at intervals during all but the winter months.

6. *Perennials*.—Vegetative period continuous with irregularly distributed maxima. Reproduction takes place during the spring, summer and autumn.

7. *Irregulars*.—Forms in which the combinations of conditions necessary for good vegetative development and reproduction occur at irregular intervals, usually of more than a year's duration.

Algæ fruit most abundantly during periods of high water following favorable conditions for vegetative development, rather than during periods of "concentration of the water," "drying up of the ponds," or the coming of "hard conditions." The drying up of pools may coincide with the

fruiting of many vernal species, but it results in decreasing the number of spores formed and the number of species that fruit.

The time of fruiting of many algæ is dependent upon combinations of environmental factors rather than on "hereditary rhythm."

A more complete account of these observations will be found in the *Transactions of the American Microscopical Society*, Vol. 32, No. 1, 1913.

*On the Presence of Diastase in certain Red Algæ:*

E. T. BARTHOLOMEW, University of Wisconsin.

In the *Florideæ*, starch granules are deposited outside the chromatophores. The granules do not usually give the characteristic reaction when subjected to iodine or zinc chloriodide, but instead turn brown to wine-red. To determine whether or not a diastase is present which will act in the ordinary way on the starch of green plants, extractions were made from the following: *Poly-siphonia variegata*, *Ceramium* sp., *Dasya elegans* and *Agardhiella tenera*. A cornstarch paste was treated with various concentrations of these extracts, and after given periods of time tested with Fehling's solution and with iodine. The results showed that although starch digestion was much slower in the tubes treated with the algal extract than in those treated with common commercial diastase, yet the digestion went on and in time was complete; usually taking from six to nine days. In the tubes treated with the algal extract the iodine color-reactions showed that probably a series of dextrans was formed before the starch was completely digested. No doubt the great viscosity of the algal extract materially retarded its action on the paste. By running a series of controls, careful check was kept on each set of experiments. It appears, therefore, that there is present in the *Florideæ* a diastase similar to that found in green plants.

*Cytological Studies on Spharoplea:* E. M. GILBERT, University of Wisconsin.

Investigation has shown that many statements made by Klebahn and Golenkin with regard to *Spharoplea* are inaccurate.

No conspicuous pit-like depressions have been found in partition walls as described by Golenkin.

Cleavage, in the formation of eggs, begins with constrictions from the plasma membrane, and cuts the cell contents into masses of varying sizes. All stages, from those having a single row of large eggs to those having a double row of small eggs may be found in one filament, indicating the possi-

bility that Klebahn saw stages in a single form and not two distinct varieties. I have been unable to find a fusion of many nuclei in the egg as described by Golenkin, nor a multinucleated egg as described by Klebahn.

All nuclear divisions are mitotic, not simply the earlier divisions as noted by Golenkin. There is no fragmentation of the nucleolus to form the chromosomes.

Fertilization does not take place until the egg is fully formed and rounded up; at this time the egg nucleus lies in the center of the egg.

The pyrenoids vary greatly as to size and shape, and the starch is often found to be very irregularly arranged around the central structure.

*A Comparison of Plant and Animal Spermatogenesis:* CHARLES E. ALLEN, University of Wisconsin.

The development of the androcyte of *Polychitum juniperinum* into the antherozoid is in several respects closely parallel to the corresponding metamorphosis of the spermatid in certain animals, notably in mammals. For present purposes comparison will be made with the spermatogenesis of the guinea-pig, well known through the researches of Meves.

1. In both spermatid and androcyte the nucleus is at first central, then comes to lie at the extreme side or end of the cell. It undergoes a great diminution in volume, its contents becoming denser and finally homogeneous. The nucleus of the spermatid is finally flattened and curved into the form of the bowl of a spoon; that of the androcyte is drawn out into a long spiral filament.

2. The spermatid possesses two *central bodies*; the androcyte contains the blepharoplast, whose centrosomic nature is a disputed question. From one of the central bodies a contractile filament grows out which becomes the axial filament of the vibratory tail. From the blepharoplast grow out two cilia. Out of the central bodies is developed the *end knob* or *middle piece* of the spermatozoon; the blepharoplast forms the anterior end of the antherozoid; in each case the part of the male cell in question is that to which the motile apparatus is attached.

3. The *sphere* or *idiozome* of the spermatid divides into two portions; one, the *acrosome*, forms the anterior end of the spermatozoon; the other, a spherical mass, passes to the posterior part of the cell and is finally discarded with other unused portions of the cytoplasm. The young androcyte contains a spherical body which, like the idiozome,

divides into two; one lies close to the anterior end of the blepharoplast, and perhaps persists in the mature antherozoid as a delicate sheath about the blepharoplast; the other, which has been called by Ikeno (incorrectly) the *chromatoid Nebenkörper* and by M. Wilson the *limosphere*, places itself in contact with the posterior end of the elongating nucleus and is discarded with the remaining cytoplasm after the antherozoid becomes free.

4. The androcyte contains a small spherical body which seems to persist but a short time and has no discoverable function; it may be compared with the *chromatoid Nebenkörper* or with the *Nebenkern* of the spermatid, both of which are conspicuous, but temporary and apparently functionless.

5. That part of the cytoplasm in both spermatid and androcyte which is not used in forming the mature cell rounds up into a vesicle; this cytoplasmic residue is discarded by the spermatozoon before maturity, and by the antherozoid after its escape from the antherid.

How far the similarities noted are due to a series of homologies, and how far to the fact that a similar problem is to be worked out by two cells similar but of widely divergent origin, must be left for the present an open question.

*Intermingling of Perennial Sporophytic and Gametophytic Generations in Rusts:* E. W. OLIVE, Brooklyn Botanic Garden.

*The Individuality of Chromosomes in the Somatic Cells of Gentiana procera:* R. H. DENNISTON, University of Wisconsin.

The nuclei in the cells of the nucellus and integument were the ones especially studied.

The material is favorable, because the chromatin appears in the resting stages in deeply stained, well-defined masses.

In this plant there is a large number of chromosomes, about eighty. These appear closely massed together in the equatorial plate stage.

In the metaphase the chromosomes are pulled away from each other toward their respective poles. In this view the chromosomes appear as short curved rods.

The chromosomes do not lose their identity in the diaster stage, as here and there an individual can be plainly seen projecting from the mass.

The long axes of the individual chromosomes conform in general direction with the long axis of the spindle.

After the closely packed condition of the chromosomes in the diaster, they move apart somewhat,

each group appearing to occupy more space. At this time no apparent change in the density or size of individuals has taken place, but their axes now lie in many directions. The nuclear membrane appears and the nucleus has the form of an oval with the shorter diameter in the direction of the spindle. It may be that the spreading apart of the chromosomes is for the purpose of facilitating their growth, as they now appear somewhat larger. Probably the chromosomes do not grow, but become less dense, since they do not stain so intensely at this time. The nucleoles make their appearance as small oval bodies, from one to four in number. These usually combine later, to form a single nucleole.

The chromosomes now appear to become angular and to lose their curved form. Threads of linin appear and portions of the chromatin appear to be drawn out along these threads. No continuous spirem is formed, however. The chromosomes now come together in groups, forming various-sized homogeneous, angular masses. This is the condition in which the chromatin is found in the greater number of so-called resting cells in the Gentian. There are also present small particles of chromatin material along the linin threads which connect the larger masses. There is no uniformity in the number of the larger masses, and in this plant there is no indication of prochromosomes, *i. e.*, there is no relation between the number of chromosomes and the number of these masses.

Each mass appears to be composed of smaller fairly distinct bodies, but these smaller bodies do not represent the chromosomes, since they are much more numerous and vary in size. These small bodies later become arranged along the linin thread, forming a spirem.

The spirem increases rapidly in diameter, takes a homogeneous stain, and occupies a peripheral position in the nucleus. Irregularities on the surface of the spirem suggest the position of the chromatin bodies of which it was made up. Segmentation of the spirem follows and the chromosomes are formed.

These are long at first, but soon shorten to rod-like bodies, three or four times as long as broad. They are distributed throughout the nucleus and pairing does not appear to take place.

The main points in the history of the chromatin in the somatic cells of this plant are:

1. The aggregation of chromosomes in the diaster, from which, later, the chromosomes separate out.

2. The absence of a dispirem.

3. The presence in the resting nucleus of chromatin masses which vary in size and shape.

4. The breaking up of these chromatin masses into smaller fragments, more numerous than the chromosomes.

*Physiological and Economic Significance of the Structure of the Tracheids of Conifers:* I. W. BAILEY, Harvard University.

The so-called striated tracheids of conifers are a specialized type of tissue structurally organized to resist compression. Gothan's hypothesis that "spiralstreifung" are spiral cracks confined to heartwood, and are produced by chemical changes and mechanical stresses in the transformation of alburnum into duramen, is not substantiated by a study of the origin and distribution of striations in the various coniferous genera.

Cracking or slitting of tracheid walls in drying occurs sporadically and is confined to the so-called summerwood. Tiemann in his "slit" theory of the penetration of gases and preservatives into seasoned wood has not taken into consideration the important fact that drying-cracks do not rupture the middle lamella and are confined to the secondary and tertiary walls. Injection experiments show that the membranes of bordered pits in freshly cut green sapwood are perforated and permeable to gases, colloids and finely divided solids held in suspension.

*The Leaf Trace and Pitting of the Araucariæ and their Relation with those of the Cordaitalean Forms:* R. B. THOMPSON, University of Toronto.

The venation of the Araucarian and Cordaitalean leaves is typically dichotomous, though in some of the modern forms a false trichotomy has been acquired. In both groups the dichotomous condition persists in the secondary wood, *double traces* extending to the pith in many instances. The bundles of the double trace are far apart in the seedling of *Agathis*. Ginkgo has been up to the present the classical example of the double trace in the secondary wood for comparison with the Cordaitalean forms. The double trace in the cortex of the Abietinæ has been considered a vestige of this condition.

In pitting, the cone and root of the Araucariæ show a more accentuated Cordaitalean character than that of the stem. The ordinary tracheids of the cone, for example, may have the pits as much as 5-seriate and extending from end to end of the tracheid. The ray-pitting of the tracheids retains

the multi-seriate condition longer than the adjacent part, where tracheid is in contact with tracheid. This is a contrast to some of the Abietineæ where the ray pitting consists of "Gross-eiporen" derived from the fusion of smaller pits.

Both leaf traces and pitting are considered as indicating the Cordaitalean connection of the Araucarineæ and as directly opposed to the derivation of the Araucarineæ from the Abietineæ. The anatomical evidence is thus in accord with the geological, since, as has been recently shown, the forms of the older strata which were thought to have been Abietinean have proved not to be authentic.

*Macrozamia Moorei, a Connecting Link between Living and Fossil Cycads:* C. J. CHAMBERLAIN, University of Chicago.

*A Possible Means of Identifying the Sex of + and — Strains in the Mucors:* A. F. BLAKESLEE, Carnegie Institution.

Certain of the hermaphroditic species of the mucors are distinctly heterogamic, forming regularly large female gametes and smaller male gametes. By growing the (+) and (—) races of an isogamous dioecious species in contrast with such an heterogamic hermaphroditic species, a sexual reaction has been found to occur between female branches of the hermaphrodite and branches of the (—) race, on the one hand, and between male branches of the hermaphrodite and branches of the (+) race on the other hand. This reaction would lead one to consider the (—) race male and the (+) race female.

*A Suggestion as to the Phylogeny of the Ascomycetes:* ERNST A. BESSEY, Michigan Agricultural College.

Of the two suggested points of origin of the Ascomycetes, the Phycmycetes are excluded in view of their non-septate plant body and the simplicity of the structures resulting from the sexual union. Many of the red seaweeds, on the other hand, have a plant body in many respects similar to that of the Ascomycetes, *i. e.*, septate with a single rather large pit or pore in the septum, the segments being in both groups either uni- or plurinucleate. In both groups, the result of the sexual union is a "spore fruit," *i. e.*, a more or less extensive mass of branches from the female cell terminating in the reproductive cells. The fact that a number of red seaweeds are known which lack chlorophyll and are strictly parasitic upon other algæ (red seaweeds), very often surrounding and separating the cells of the host in

a manner similar to that shown by the lichens with reference to their hosts and the fact that in the reproduction of the latter group, *e. g.*, *Collema*, the male elements are, as in the red seaweeds, non-motile sperm cells, suggests that lichens may represent a group derived from some of the more primitive red seaweeds, probably inhabitants of fresh water, that became parasitic upon colonies of Nostoc or other algæ and gradually assumed the terrestrial habit. The apothecium would correspond to the cystocarp and the ascus would phylogenetically have some relation to the carpogonium. From such lichens have been derived then the non-lichen Discomycetes, on the one hand, and perhaps through the closing and becoming more firm of the apothecium, may have arisen the Pyrenomyces. Similarly the teliospores of the rusts and smuts would be homologous to the carpogonium.

*Morphogenesis in Pedicellaria:* R. A. HARPER, Columbia University.

In the genus *Pedicellaria* we find all degrees of variation in cell differentiation from species in which the colonies are composed of cells which are practically all alike to others in which only the peripheral cells are provided with well-developed spines, while in the central region the spinous projections are only slightly indicated by the kidney-shaped form of the cells with the reentering angle on the outer side. In the species with uniform cells these may show either very long spinous processes or almost none at all. The reproduction of the colonies by motile zoospores, which after swarming for from five to fifteen minutes arrange themselves spontaneously in the plate-shaped new colony shows that as in *Hydrodictyon* the form of the colony is not predetermined by any spatially differentiated representation of the adult in the organization of the germ plasm. The cells arrange themselves in accordance with the principle of least surfaces modified by their specifically inherited cell form and the law of reproduction by bipartition. All the cells of a given species are in general alike in their inherited form and capacities for differentiated growth, and are totipotent. The differentiation between cells in species which show it is due to cellular interaction in the formation and growth of the colony. This morphogenetic equivalence of the cells is most clearly shown in cases in which the cells are abnormally or unusually situated as a result of unfavorable environmental conditions. All the species share an inherited tendency to produce one or two spines

on one side of the cell. The degree to which these spines are developed in a given colony is determined by cellular interactions. The degree to which the tendency is present in different species is the basis for the delimitation of species in the genus. All the cells show also a polar differentiation, the spines being produced in the direction of the shorter of the two major axes of the cell. There is some evidence also of specifically oriented attractions between the cells such that the spines in normal individuals come to point radially outward in the interior as well as in the peripheral cells of the colony. Specifically inherited cell form and cellular interactions during growth are the principal morphogenetic factors in the development of the differentiated cell colonies of *Pediastrum*.

*Tetrademus*, a New Four-celled Cœnobic Alga:  
G. M. SMITH, University of Wisconsin.

*Tetrademus* resembles *Scenedesmus* in the number and shape of the cells, but differs from it in the cellular arrangement, the cells being in two planes, each plane containing two cells.

The reproduction is by autocolonies. The first cleavage of the mother cell is transverse and the second is in the same plane and diagonal to the line of the first cleavage. After the four daughter cells have been formed by cleavage they elongate, while still within the mother cell, taking the same relative position that they have in the mature colony. The young colony is liberated by a longitudinal rupture of the mother cell wall.

The mature cell possesses a nucleus and a pyrenoid. The nucleus divides once before the first cleavage takes place, but the pyrenoid does not. When the four daughter cells have been formed, the old pyrenoid of the mother cell is found in one of them while the other three contain no pyrenoid. This pyrenoid then disappears and pyrenoids are formed *de novo* at the time that the daughter cells are elongating prior to their liberation from the old mother cell wall.

*The Relation of the Lichen to its Algal Host*:  
BRUCE FINK, Miami University.

The common algal hosts of lichens; finding the algal hosts growing near lichens in nature; cultures of lichens from spores and spermatia with and without the algal hosts; cultures of the algal hosts separately; growth of lichen hosts and other algae on media with and without light and carbon dioxide; breathing pores and other means of aeration of the algal hosts in lichens; lichens as carriers of food to the algal hosts; hypotheses regard-

ing the relationship of the lichen and its algal host, with evidence from recent research.

*A Dry Rot of the Irish Potato Tuber*: E. M. WILCOX, University of Nebraska.

In 1908 our attention was called to the fact that potatoes grown in western Nebraska were often seriously injured by a form of rot during storage. Comprehensive investigations were undertaken to learn the exact cause and nature of this disease. It was found to be due to a new species of *Fusarium*, shortly to be published as *Fusarium tuberivorum* Wilcox and Link. Numerous inoculation experiments have established the causal relation of this organism to this tuber dry rot. The organism is, however, unable to invade any other part of the plant than the tuber, and the tuber only when it is practically mature.

*The Propagation of Medicinal Plants*: F. A. MILLER.

*An Optimum Culture Medium for a Soil Fungus*:  
J. B. POLLOCK, University of Michigan.

The work was done in collaboration with Miss Rose M. Taylor, and had for its object the determination of an optimum culture medium of exactly known composition and of simple constitution. The fungus chosen was one isolated from the soil by H. N. Goddard, and determined as a new species of *Myceliophthora*, to be described by him elsewhere under the name of *Myceliophthora sulphurea*. The medium aimed at was one with the fewest and simplest compounds which would furnish the chemical elements necessary for the growth of fungi. It is known that fungi will grow with as few as eight of the known elements, namely, carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, potassium and magnesium. In the experiments sixteen organic compounds were tested as to their availability for carbon, and incidentally they could also supply hydrogen and oxygen. These carbon compounds were saccharose, dextrose, maltose, inulin, lævulose, arabinose, mannite, cellulose, resin, starch, glycocoll, alanin, asparagin, glycerine, potassium tartrate and sodium benzoate. The compounds tested as to their availability for nitrogen were ammonium sulphate, ammonium nitrate, sodium nitrate, potassium nitrate and calcium nitrate. In all the cultures magnesium sulphate was used to supply magnesium and sulphur. This was used in only one concentration, 1/1000 that of a gram-molecular solution = 1/1000 M. Mono-potassium phosphate was used to furnish phosphorus and potassium, and it was used in several concentrations, 1/10,

1/25, 1/50 and 1/100 M. Nitrogen compounds were used in concentrations of 1/5, 1/25, 1/125, 1/250 and 1/500 M. Preliminary experiments soon showed that this fungus could not obtain carbon from several of the compounds tried and that others had only slight availability. Only maltose, saccharose and dextrose were tried out for final results, in concentrations of 1, 2/5, 1/5, 1/10, 1/25, 1/125, 1/250, 1/500, 1/625 M.

Twenty-four sets of cultures were carried through, the number of flasks in a set ranging from six to forty-eight. The test applied for the optimum medium was the amount of vegetative growth, estimated by the eye alone in the early stages of growth for all the cultures, but in cases where the results were doubtful and also for the purpose of getting quantitative results for some of the work, in several sets the growth was determined by weight.

*Conclusions.*—Of the nitrogen compounds tried calcium nitrate was the best. Its best concentration was 1/250 M. 1/125 and 1/500 M were nearly as good. Sodium nitrate was next best, ammonium sulphate was very decidedly the poorest. In the early stages of growth ammonium nitrate was little better than ammonium sulphate, but given a longer time it became equal to potassium nitrate, and the latter was only slightly below sodium nitrate.

The different concentrations of the phosphate had little influence on the amount of growth, 1/10, 1/50 and 1/100 M being almost equally good, except that with cellulose as the carbon compound little growth was made with the concentration of the phosphate 1/50 or 1/100 M, while there was very good growth in 1/10 M.

Among the carbon compounds maltose was decidedly the best when ammonium nitrate was the source of nitrogen, but with calcium nitrate saccharose was as good or better. For all the three carbon compounds saccharose, dextrose and maltose, the concentration of 1 M was strongly inhibitive of growth. In 1/5 M the growth was far better than in any of less concentration. The experiments in which 2/5 M was used gave a slightly greater total than 1/5 M, but the rate of growth in the former was decidedly slower than in the latter. It was true in a good many sets of cultures that the rate of growth was more rapid in the more dilute solutions, though maximum growth occurred in more concentrated solutions.

Of the substances and concentrations tried the optimum medium for the fungus tested was:

Saccharose .....	2/5 M.
Calcium nitrate .....	1/250 M.
Monopotassium phosphate ...	1/10–1/100 M.
Magnesium sulphate .....	1/1000 M.

Saccharose has one very decided advantage over both dextrose and maltose. It may be obtained in a purer form. The ordinary rock candy obtainable at any candy store is far more nearly chemically pure than the grades of maltose and dextrose obtained from reliable dealers and labeled C.P. This is a very decided advantage in critical culture experiments.

*A Labeling Surface for Laboratory Glassware:*  
A. F. BLAKESLEE, Carnegie Institution.

Diamond ink applied to glassware gives a permanent ground-glass surface upon which labels can be written with lead pencil. Labels upon this surface are of especial value upon flasks, test tubes, etc., that need to be sterilized in autoclav.

GEORGE T. MOORE,  
Secretary

#### SOCIETIES AND ACADEMIES

##### THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 465th regular meeting of the Anthropological Society of Washington, D. C., was held at Room 43 of the new building of the National Museum at 4:30 P.M., January 21, 1913, Mr. George R. Stetson, the president, in the chair.

Dr. Tom. A. Williams, M.B., C. H. Edin., M. Corresp. Etrang. Soc. de Neurologie de Paris, Soc. de Psychol. de Paris, etc., charter M. Am. Psychopath. Assoc., Collaborator *Jour. Abnorm. Psychol.*, read a paper on "The Dream in the Life of the Mind."

Trance, vision, ecstasy and disease-delirium are closely allied to the dream state. The psychopathology of them all illuminates formerly uncomprehended diseases. In a dream (illustrated by a case) mental perturbation may crystallize, as it were, and lead to rampagous behavior. On the contrary, dreams may be teleologically beneficial; as where a vision saved a young woman from suicide, as was the case also with Benvenuto Cellini.

They are more often a mere reproduction of former experiences, more or less significant and more so in psychopathic individuals, such as in a young hysteric who dreamed of falling down wells, assassinations and deaths, all painful experiences of her childhood.

Their sexual nature, believed inevitable by a certain school, is not so regarded by the author.

Nor is their analysis an essential of proper diagnosis and treatment of psychopathies. But in some cases they render the investigation more easy.

Dream-thought, apparently confused, is really significant of the mental trend of the individual, when properly analyzed and interpreted. One dreams all the time, but recollects only that within seven minutes of waking. The form of dream can be determined by external stimuli. This is demonstrated in spite of its contradiction by some psychopathologists.

A SPECIAL meeting of the Anthropological Society of Washington was held on February 4, 1913, at 4:30 P.M. in Room 43 of the new building of the National Museum, the president, Mr. George R. Stetson, in the chair.

Dr. Clark Wissler, curator of the department of anthropology in the American Museum of Natural History, New York, read a very elaborate and philosophical paper on the "Doctrine of Evolution and Anthropology."

An attempt was made to distinguish between cultural phenomena on one hand and biological on the other, especially to make clear that cultural phenomena are not inherited, though the instinct to develop culture, or to invent, is most certainly inborn. It was suggested that the historical attitude of present-day anthropology should be taken as expressing the cultural point of view. Culture itself seems to be associated habit complexes or constructs of the mind and not to be in any way innate or inborn, but to be an external affair, preserved and carried on entirely by learning or educating processes. Cultures develop and have an evolution of their own, but since they are not inherited they can not be considered parts of a biological development. They are most assuredly facts of another order. Being products of the mind, the only limitations put upon them are to be sought in the mind itself and since psychologists tell us that we have in the main only an associated cultural whole, resolvable into psychological elements and since this, in turn, is only a matter of invention and not of cell differentiation. Being a matter of invention, the genetic relationship becomes purely a matter of history, since we can not foretell what the relationship is.

The psycho-physical mechanism of man is biological and innate and constitutes man's equipment for the production of cultures. Anthropology holds that the mechanism is general in so far as it is not limited to any particular culture, and that it enables the individual to practise any cul-

ture he may meet, though not necessarily to equal degrees.

When we come to consider the biological theory of evolution we find that it applies to the psycho-physical mechanism but not to culture. For cultures we must have another point of view or theory and this in America, at least, is the historical or cultural conception. This conception is in general that cultural traits are the results of invention, a mental process, and their development or evolution is to be taken as a historical and psychological problem.

The paper was briefly discussed by Dr. Folkmar, Dr. Swanton and Dr. Hough.

WM. H. BABCOCK,  
*Secretary*

#### PHILOSOPHICAL SOCIETY, UNIVERSITY OF VIRGINIA MATHEMATICAL AND SCIENTIFIC SECTION

THE third meeting of the session 1912-13 of the Mathematical and Scientific Section was held on December 16.

Professor A. H. Tuttle made a preliminary report of work now in progress upon the life-history of the Charales, based chiefly upon cytological studies of a species of *Tolyella*.

The fourth meeting of the session 1912-13 of the Mathematical and Scientific Section was held on January 20.

Professor J. T. Singewald, of the Johns Hopkins University, read a paper on "The Titaniferous Ores of the United States."

WM. A. KEPNER,  
*Secretary*

#### UNIVERSITY OF VIRGINIA

#### THE ELISHA MITCHELL SCIENTIFIC SOCIETY

THE 203d meeting of the society was held in Chemistry Hall, University of North Carolina, on Tuesday evening, February 11. The following program was presented:

"Photography of Sound Waves," by Mr. A. H. Patterson.

"Difference in the Effect of Grehant's Anesthetic and of Morphine Ether on the Output of Urine by Nephritic Animals," by Dr. W. B. MacNider.

"The Chemical Action of Light," by Dr. A. S. Wheeler.

## THE PRINCIPLES OF BIOLOGY

By J. IRVIN HAMAKER, A.M., PH.D.

*Professor of Biology in the Randolph-Macon Woman's College.*

Will be published  
EARLY IN APRIL

Thoroughly illustrated with many Original Pictures.

It is a one year course presenting the salient features in the organism of plants and animals, and bringing out important biological principles. It is designed to supplement practical work in the laboratory and field, and to relieve the student of much note taking. Purely descriptive matter is reduced to a minimum and examples are omitted because the teacher will have a fund of local and familiar illustrations from which to draw, to the greater benefit of the student.

THE SUBJECT IS PRESENTED IN THREE PARTS :

1. The structure and function of plants.  
The method in this part is to build up from the familiar to the less familiar.
2. The structure and function of animals.  
The discussion here is largely by comparison.
3. General biological questions ; Protoplasm and its activities, development, evolution, special adaptations, etc.

No laboratory work is included in the discussion, thus giving the text greater continuity and readability. An outline of experiments is inserted at proper points in the book, planned to precede the study of the text matter.

The book is intended as a first course both for students who intend to continue in the science and for those who desire merely an elementary cultural view of the subject.

## THE REGULATION OF NEUTRALITY IN THE ANIMAL BODY<sup>1</sup>

It was a favorite figure of Cuvier's, recurring again and again in his works,<sup>2</sup> to compare life with a vortex into which molecules continually enter, from which they continually depart; meantime the vortex remains, and thus the form of a living thing appears to be more important than the substance. Cuvier's analogy, though almost forgotten, is quite as valid to-day as a century ago, but I suspect that the modern physiologist will be disposed to see in such a view a justification of the study of *conditions* rather than a claim for morphology. What, indeed, is the importance of the anatomy of a whirlpool in comparison with the dynamics thereof?

Now it is the study of conditions within the organism which physical chemistry has contributed to physiology—solution, surface tension, the colloidal state, osmotic pressure, ionization, alkalinity or neutrality—and these are dynamical equilibria rather than in any sense morphological elements. To such conditions Cuvier's figure exactly applies, and provides, moreover, the very best means for their systematic investigation; while the conditions, in turn, most fully reveal that which was partly made clear to Cuvier by the imagination of genius, and, in spite of it, quite certainly in part unknown to him.

The right working of physiological proc-

<sup>1</sup> Read in the joint meeting of Section K of the American Association, the American Physiological Society and the American Society of Biological Chemists at Cleveland.

<sup>2</sup> See Merz, "A History of European Thought in the Nineteenth Century," Vol. I., p. 129.

esses depends, then, upon accurate adjustment and preservation of physico-chemical conditions within the organism. Such conditions as temperature, molecular concentration and neutrality are now known to be nicely adjusted and maintained; adjusted by processes going on in the body, maintained by exchanges with the environment. This paper is concerned with those physiological processes whereby the normal reaction of the body fluids is permanently preserved.<sup>3</sup>

Throughout the human body, while life exists, there occurs a regular formation of acid substances, excretory products of metabolism. As they form, these various matters, carbonic acid, sulphuric acid and phosphoric acid in the main, immediately combine, but only partially, according to their several avidities, with the basic constituents of protoplasm and blood. In pathological conditions great quantities of acetoacetic acid and  $\beta$ -oxybutyric acid may be produced and claim their share of base. At irregular intervals varying quantities of acids and bases pour in with the food. Thus, through resulting changes in equilibria between bases and acids, normal metabolism steadily operates to lower the unvarying alkaline reaction (almost neutrality<sup>4</sup>) of the body. This tendency to acidity is held sharply in check by special protective mechanisms, acting coordinately, in cooperation and regular succession.

The chemical reactions whereby such material is first neutralized, the chemical substances which aid in neutralization, the shares of more important substances in the

process, and their efficiency, the changes in chemical equilibria, including resulting changes in hydrogen and hydroxyl ion concentrations, all, *so far as they concern true solution*, are known with a fair approach to certainty. Principally this work of neutralization is done by salts of phosphoric and carbonic acids, with aid from the amphoteric proteins. In simplified form the process may be represented by the two reactions,

where  $M$  stands for any basic radical,  $A$  for any acid radical. Other less important simultaneous reactions are of the same type, except perhaps the union of the weak acids with basic proteins like globine, and the union of bases with more acid proteins. Through the remarkable circumstance that phosphates and carbonates possess, among all known chemical substances, the highest power to preserve neutrality in solution,<sup>5</sup> this function is so well performed that the alkaline reaction of the body scarcely varies, even when the load upon the mechanism is heavy.

But, however efficient such an arrangement may be, it is of its very nature only the first stage in the process of the excretion of acid, and wholly dependent upon constant support by the kidney, and of course upon a supply of alkali in the food. Regularly, as they form, the acid bodies must be afforded alkali by blood and protoplasm, for every molecule of carbonic acid about 0.93 molecule of alkali, for every molecule of phosphoric acid 1.89 molecules of alkali, and for every molecule of sulphuric acid 2 molecules of alkali, in accordance with chemical laws and the normal reaction of the body. Clearly, therefore,

<sup>3</sup> See L. J. Henderson, "The Theory of Neutrality Regulation in the Animal Organism," *American Journal of Physiology*, XXI, 427, 1908, and "A Critical Study of the Process of Acid Excretion," *Journal of Biological Chemistry*, IX, 403, 1911.

<sup>4</sup> The terms may be used interchangeably for an alkalinity which is so slight.

<sup>5</sup> L. J. Henderson, *American Journal of Physiology*, XXI, 173, 1908.

this neutralization must rest upon physiological processes which serve to reestablish the original conditions, for if such great amounts of alkali were discharged from the body with the acid excretory substances, the organism would lose its protection and acidity would speedily ensue throughout the system. Thus an imperative necessity arises for the retention of a part of the alkali which serves as a carrier in the process of removing acid from the body. Of course the necessary magnitude of such alkali retention by the kidney varies with the net amount of alkali ingested and with the acid formation of the body.

The conditions in man are closely paralleled by those in other higher animals, and there is reason to believe that constancy of alkalinity is quite the earliest and most universal physico-chemical regulation of active protoplasm. In fact, as the investigations of Palitzsch<sup>6</sup> show, the ocean itself is likewise quite constant in its alkalinity. It is worthy of note that this is due to the simultaneous presence of carbonic acid and bicarbonates in the sea water, a fact which lends support to Macallum's ideas about the derivation of the body fluids. Thus active protoplasm everywhere, as well as that which surrounds it—the environment and the *milieu intérieur*—appear to be and to have been always of stable reaction.

According to the modern theory of solution water itself, like the dissolved electrolytes, is dissociated into ions, though only to a very slight degree. The reaction is expressed thus:

If the water be pure the concentrations of hydrogen and hydroxyl ions are neces-

sarily equal, for water is electrically neutral. A variety of independent methods of estimation have shown that at 25° this concentration amounts almost precisely to N/10,000,000 in the ordinary units. This corresponds to 0.0000001 gram of ionized hydrogen and 0.0000017 gram of ionized hydroxyl in 1,000 grams of water. Further, the theory of solution explains acidity in water by the occurrence of hydrogen ions, formed from dissolved electrolytes, in excess of hydroxyl ions; and alkalinity by a similar excess of hydroxyl over hydrogen ions. Neutrality is, accordingly, the condition when, as in pure water, the two concentrations are equal. In short, expressing the concentration of ionized hydrogen by ( $\dot{\text{H}}$ ) and of ionized hydroxyl by ( $\text{O}\bar{\text{H}}$ ), if

$$(\dot{\text{H}}) = \frac{\text{N}}{10,000,000} = (\text{O}\bar{\text{H}})$$

the solution is neutral. If

$$(\dot{\text{H}}) > \frac{\text{N}}{10,000,000} > (\text{O}\bar{\text{H}})$$

the solution is acid. If

$$(\dot{\text{H}}) < \frac{\text{N}}{10,000,000} < (\text{O}\bar{\text{H}})$$

the solution is alkaline.

It remains to point out that implicit in these definitions is the well-founded hypothesis that in water the concentrations of hydrogen and hydroxyl ions vary inversely, so that, with constant temperature, under all circumstances their product is constant:

$$(\dot{\text{H}}) \times (\text{O}\bar{\text{H}}) = \text{K}.$$

Thus the nature of acidity and alkalinity may readily be represented by a straight line with the neutral point at its center, acidity increasing in one direction, and alkalinity in the other.

Whenever a weak acid is present in aqueous solution in company with such bases as sodium, potassium, calcium, magnesium, etc., which are invariable constitu-

ents of the ocean, blood, protoplasm, etc., *provided the acid be in excess*, it is a simple matter to determine the reaction, which can best be measured by the values of ( $\bar{H}$ ) and (OH), following the considerations above.

For this we possess a host of reliable data and a tried and well-seasoned theory—the mass law. Now there is, in connection with the application of the mass law to ionization, a certain characteristic property of an acid, its ionization constant,  $k$ , which measures its tendency to dissociate in aqueous solution, thereby to produce hydrogen ions, and hence to increase the intensity of acidity. Strong acids have ionization constants which are of the order of magnitude of 1.0, weak acids of the order of magnitude of 0.0001, the weakest acids, 0.00000001, or less.

TABLE OF IONIZATION CONSTANTS

HCl, HNO <sub>3</sub> , etc. ....	1
H <sub>3</sub> PO <sub>4</sub> .....	0.011
H <sub>3</sub> AsO <sub>4</sub> .....	0.005
HNO <sub>2</sub> .....	0.0005
H <sub>2</sub> CO <sub>3</sub> .....	0.0000003
NaH <sub>2</sub> PO <sub>4</sub> .....	0.0000002
H <sub>2</sub> S .....	0.000000091
H <sub>3</sub> BO <sub>3</sub> .....	0.0000000007
Na <sub>2</sub> HPO <sub>4</sub> .....	0.0000000000036

It has been discovered that in the general case above discussed of weak acid and salt, the concentration of ionized hydrogen is always almost exactly proportional to the ratio of free acid to salt, and is equal, in very close approximation, to the product of this ratio by a number slightly greater than the ionization constant of the acid. That is to say, representing free acid by  $HA$  and salt by  $BA$ ,

$$(\bar{H}) = k \times \frac{HA}{BA},$$

whence, if  $k = (\bar{H})$

$$\frac{HA}{BA} = 1.$$

From this relationship therefore follows the conclusion, fully established by experiment, that whenever in such a solution the excess of acid,  $HA$ , is chemically equivalent to the quantity of salt,  $BA$ , the hydrogen ion concentration is almost exactly equal to the ionization constant of the acid, and this is one of the very best methods quickly to detect and characterize an acid. But the ionization constant of carbonic acid (first hydrogen atom) at room temperature is 0.0000003. Hence, in a solution containing exactly equivalent quantities of free carbonic acid, for example, sodium bicarbonate, the hydrogen ion concentration must be approximately 0.0000003 N. Further, since

$$\frac{HA}{BA} = \frac{(\bar{H})}{k},$$

if the amount of acid be ten times the amount of salt

$$\left( \frac{HA}{BA} = 10 \right)$$

the hydrogen ion concentration must be about 0.000003 N, and if the reverse be the case

$$\left( \frac{HA}{BA} = \frac{1}{10} \right)$$

the value must be nearly 0.00000003 N.

The range of variation of concentration of hydrogen ions in the usual solutions of the chemical laboratory considerably surpasses the limits of 1.0 N and 0.00000000000001 N. In comparison with such enormous differences those between 0.000003 N and 0.00000003 N are almost negligible (1/100: 1/100,000,000,000,000). Hence ordinarily it is quite accurate enough to speak of any

solution containing both free carbonic acid and a bicarbonate, when the disparity between the concentrations of the two substances is not very great, as of constant reaction. For, obviously, the neutral point, which at a temperature of 25° amounts to a concentration of hydrogen and hydroxyl ions 0.00000001 N, falls well within the narrow range of reaction of such solutions, being characterized by a ratio of carbonic acid to bicarbonate of about 1:3.

Thus carbonic acid, like the almost equally weak acid, phosphoric acid (after its first hydrogen has been neutralized by base), has the remarkable property of preserving a neutral reaction whenever it exists in solution with its salts, provided there be an excess of acid. All acids whose strength is even a little either greater or less than carbonic acid lack the property. There is nothing mysterious about this fact; any other weak acid will hold constant the reaction in its own range of reaction; thus acetic acid in the neighborhood of a hydrogen ion concentration N/100,000, etc.

This characteristic of carbonic acid is of the utmost significance, first by regulating one of the most fundamental of physico-chemical conditions, and secondly, by preserving throughout nature the characteristic chemical inactivity of water, which disappears whenever the reaction becomes either appreciably acid or appreciably alkaline. Almost the only case of important geological action due to acidity or alkalinity of water is the action of fresh water, containing carbonic acid itself, to weather the rocks. This process is however self-limited, for the dissolved material forms bicarbonates, and thus at once provides permanently balanced solutions.<sup>7</sup>

<sup>7</sup> L. J. Henderson, "The Fitness of the Environment," Chapters IV. and V. New York, The Macmillan Company, 1913.

Elsewhere, within and without the organism, carbonic acid is almost always accompanied by bicarbonates, and a close approach to neutrality is the result. In the organism the variation in ratio of phosphates is similar to the case of the carbonates, as may readily be illustrated by experiment. Thus a solution consisting of equal parts of monosodium phosphate and disodium phosphate will be found to give a neutral reaction with both methyl orange and phenol phthalein, and the neutrality, thus indicated, will not be disturbed by the addition of relatively large amounts of either acid or alkali.

We may next consider the equilibrium within the organism, where the concentration of ionized hydrogen can undoubtedly vary between 5 N/100,000,000 and N/10,000,000, but during life probably not much more widely, in the body at large. At body temperature the most probable values of the ionization constants of the acids in question yield the equations:

$$(\dot{H}) = 6.9 \times 10^{-7} \times \frac{H_2CO_3}{NaHCO_3},$$

$$(\dot{H}) = 2.1 \times 10^{-7} \times \frac{NaH_2PO_4}{Na_2HPO_4}.$$

If

$$(\dot{H}) = 0.5 \times 10^{-7} N$$

$$\frac{H_2CO_3}{NaHCO_3} = \frac{1}{13.8}, \quad \frac{NaH_2PO_4}{Na_2HPO_4} = \frac{1}{4.2},$$

and if

$$(\dot{H}) = 1.0 \times 10^{-7} N$$

$$\frac{H_2CO_3}{NaHCO_3} = \frac{1}{6.9}, \quad \frac{NaH_2PO_4}{Na_2HPO_4} = \frac{1}{2.1}.$$

In short, in order to bring about this seemingly insignificant change in reaction, the relative quantities of acid and base in the body must undergo very great changes; or, otherwise stated, until very large quantitative changes in the amount of acid or base in the body have come about, there can be no appreciable change in the reaction.

In the case of carbonic acid the equilibrium is further complicated by the activity of the lung in excreting the free acid and regulating the concentration of that substance, which is kept nearly constant. Thus, when acid reacts with bicarbonate in the body, it diminishes the latter substance without increasing the amount of the acid. In this manner through the escape of carbonic acid, the efficiency of the equilibrium in the preservation of neutrality is further greatly increased. Thus it is that even in extreme acid intoxication, as for instance diabetic coma, almost the only chemical change that can be detected, as a result of the action of enormous quantities of acid through long periods of time, is a large diminution in the bicarbonates of the blood; in the instances above calculated this would amount to a decrease of about 50 per cent. in the total carbonic acid. Meantime about 20 per cent. of the phosphoric acid of the body will probably be changed from alkaline to acid phosphate, and the proteins will have given up a portion of the alkali with which they are combined.

The recognition of the fact that diminution of bicarbonates is the principal effect of acid intoxication upon the blood, involves important consequences. On the one hand it has become clear that the therapeutic use of sodium bicarbonate is desirable in a large variety of pathological conditions and, on the other hand, it seems to be certain that the evil effects of acidosis largely depend upon interference with the transport of carbonic acid and its excretion from the body. In truth this equilibrium is intimately associated with the respiratory function, and with a great number of other fundamental physiological activities, and with the osmotic pressure of the cell.

Further the profound influence of hy-

drogen and hydroxyl ions upon many enzymatic processes, and upon colloids in general has been established, and it is gradually becoming clear that all the physico-chemical conditions in protoplasm—alkalinity, osmotic pressure, colloidal swelling, chemical equilibrium, temperature—are interdependent, and that carbonic acid and the acid-base equilibrium are among all these things probably the most important variables.

The reason why it may be asserted that carbonic and phosphoric acids and the proteins are the only important substances which are involved in the physiological regulation of neutrality is that, for the body as a whole, in the narrow range of reaction which can actually occur, these substances can neutralize about 30 liters of 0.1 N acid, and nothing else except other substances of like ionization constants, in equal concentration, even with the advantage of the escape of acid, can do as much.

It can not be too strongly emphasized that this conclusion applies only to the true aqueous solutions of the body. Of the colloidal phase we have no knowledge, but it is evident that they may act as reservoirs of supply and as vehicles of escape.

It is also evident that, if enough acid be produced locally, for instance, lactic acid in the muscle, the protective mechanism may be overthrown, and true acidity result. There is an important connection between this consideration and theories of fatigue and muscular contraction.

But, as for the assertions themselves, they rest upon one of the immutable properties of matter. Phosphoric and carbonic acids in solution everywhere possess this characteristic, independent of the presence of everything else, just as they everywhere possess their characteristic chemical composition.

Thus it is that the regulation of reaction of blood and protoplasm manifests the very highest stability.\*

In exactly the same way that neutrality is favored by the ionization constant of phosphoric acid, the excretion of acid is facilitated. By variation of the relative amounts of acid and alkaline phosphates the relative amounts of acid and basic constituents of the urine may be varied in the highest degree, accompanied by the very smallest possible variations of hydrogen ion concentration. Thus the presence of phosphoric acid makes of the urine an ideal regulatory apparatus for the preservation of the normal ratio of acid to base in the blood.

Such are the more striking aspects of this subject. Neutrality is quite as definite, quite as fundamental and quite as important a characteristic of the organism as its temperature, or osmotic pressure, or in fact anything else that we know. And it turns out to possess those remarkable characteristics of stability that have been revealed by the researches of Rubner and others in the case of temperature, only in far higher degree.

Within wide limits of amount any acid or base may be poured into the organism, and the reaction will not vary; nor will it vary if such be produced by the organism, and this constancy will protect all enzymatic processes, the function of respiration and the whole distribution of material throughout the body.

Let us return to Cuvier's vortex. Into it let us pour anything, for example hydrochloric acid. No sooner has it entered than it is neutralized, and neutralized it remains until, on leaving the body, it appears as

sodium chloride, ammonium chloride and a slightly heightened excess of acid phosphate over alkaline phosphate in the urine.

The urine is variable, the ingesta are variable, even the products of metabolism are variable; but, while life endures, the dynamical equilibrium of hydrogen and hydroxyl ionizations persists.

L. J. HENDERSON

HARVARD UNIVERSITY

---

THE PHYSIOLOGICAL SIGNIFICANCE OF  
SOME SUBSTANCES USED IN THE  
PRESERVATION OF FOOD<sup>1</sup>

Food preservatives are those substances which delay or prevent the decomposition of food as a result of the action of bacteria or other ferment-producing organisms. Other substances, sometimes classed as preservatives, and in the popular mind associated with them, are not so much preservatives as agents for the conservation of some special property of the food in question, as, for example, the use of copper sulphate in the fixation of the color of green vegetables. A large number of bodies may be included under the head of preservatives, but our interest to-day centers in the so-called "artificial" or "chemical" preservatives, because of the question of the permissibility of using them. Some of these bodies have been condemned largely because of their origin, because of their artificial character, which basis of condemnation can not be regarded as sufficient or scientific.

Their merits or faults must be decided on the basis of physiological behavior, essentially, and from this point of view I wish to speak of several substances concerning which the discussions have been

\*For a larger survey of this whole subject two articles in the *Ergebnisse der Physiologie*, VIII., 254, 1909 (the author) and XII., 393, 1912 (Sørensen) may be consulted.

<sup>1</sup>A paper read before the Fifteenth International Congress on Hygiene and Demography, Washington, September 23, 1912.

the most heated. These discussions will be necessarily brief.

#### SODIUM BENZOATE

On certain phases of the behavior of sodium benzoate there is an abundant literature. Following the pioneer investigations of Meissner and Shepard, and Bunge and Schmiedeberg on the synthesis and estimation of hippuric acid it was recognized that benzoic acid, cinnamic acid, quinic acid and other bodies are normally combined in the animal organism with glycine and excreted as hippuric acid. It was shown, also, that many aromatic fruits and vegetables contain these organic acids which go into the benzoyl combination. Numerous later studies have shown the extent of the glycine, or potential glycine, available in the human body for combination.

With the recognition of this normal character of the hippuric acid synthesis no great objection was raised to the administration of large doses of the benzoate in certain diseases, and going back some thirty years we find a considerable record of clinical experience on the dosage of benzoates in pulmonary tuberculosis, rheumatism and diphtheria. It was shown by many physicians that doses of 5 to 25 grams a day might be given without apparent harm to the patient. This extended experience was sufficient to show that the toxic effect of the benzoate was of a very low order, not much greater possibly than that of sodium chloride.

At the time when sodium benzoate was considered important therapeutically the question of its use as a food preservative had not arisen, and the interest attaching to it then and through the following discussions was in no wise influenced by the present practical question. To what extent may benzoic acid be combined or de-

toxified in the animal organism? The earlier observers soon recognized that ordinarily and normally it combines with glycine to form hippuric acid, and the question of the available supply of this amino acid was discussed for a long time. In 1898, in experiments on rabbits, Wiener<sup>2</sup> concluded that while large doses of benzoic acid, about 1.7 gram per kilogram of body weight, were usually fatal, smaller amounts and up to the quantity yielding 1 gram of hippuric acid per kilogram of body weight, were combined and detoxified. He believed that the value for the combined benzoic acid, that is, the hippuric acid, was rather constant, the maximum being the 1 gram per kilogram of weight. The usual figures were between 0.7821 and 0.8345 gram per kilogram. From this he concluded that the available supply, or stored-up glycine, must amount to 0.3276 to 0.3496 gram per kilogram of weight. He observed that free benzoic acid appeared in the urine when amounts in excess of the maximum values quoted were ingested.

These observations were made at a time when glycine was looked upon as an important intermediary product of protein metabolism, and before much was known concerning the quantitative relations of the amino acids in the protein molecule. It was later shown that the mean glycine content of the ingested proteins is not far from 4 per cent. of their weight, and that the benzoic acid combined to form hippuric acid may be far greater than the weight corresponding to this glycine content. A stored-up reserve of glycine was for a time assumed to account for the remarkable hippuric acid formation reported by several observers, but this view has been pretty generally abandoned. In this connection the researches of Parker and Lusk,<sup>3</sup>

<sup>2</sup> *Schmied. Arch.*, 40: 313.

<sup>3</sup> *Am. Jour. Phys.*, 3: 472.

Wiechowski,<sup>4</sup> Cohn,<sup>5</sup> Magnus-Levy,<sup>6</sup> Lewinski<sup>7</sup> and others, should be referred to. All of these observers found that in the increased ingestion of large amounts of benzoic acid in animals there was an increased protein metabolism, with increasing amounts of the benzoic acid not combined as hippuric acid. In the Lewinski investigations rather large weights of benzoic acid, as the sodium salt, were given to men. In one case a man of 59 kilograms weight took 12 grams of the acid in 12 hours. All was excreted in combined form and no increase of reducing substances in the urine was noted. This amount of acid is nearly one fifth of a gram per kilogram of body weight, and is relatively less than was ingested in many of the animal experiments. If all combined with glycine it would call for 7.38 grams of the latter, or the glycine existing in about 200 grams of mixed proteins. This amount is probably more than was metabolized in the individual in question.

In another case of Lewinski's a man weighing 67 kilograms took 20 grams of the acid in 12 hours. The urine examination showed the same result as in the other case. Later, the same man took 25 grams of the acid, but it was not all combined, as 1.65 grams were recovered from the urine. When the ingestion was increased to 40 grams still more appeared in the urine uncombined with glycine. In one case on the 40-gram dosage nausea and headache were noted, but these effects seemed less marked with a diet rich in protein. The author concludes that on a high protein diet more benzoic acid may be ingested without ill effects. In one case a

man took 50 grams without apparent disturbance, but over 8 grams appeared in the urine uncombined.

All these experiments demonstrate that in man, as well as in animals, ingested benzoic acid may be detoxified in amounts which much more than correspond to the glycine of protein that may be metabolized normally in the same individual, in the same time. The 20 grams of benzoic acid given in one experiment, and which left no free acid in the urine, would correspond to 12.3 grams of glycine.

These papers have been cited because they show the remarkable capacity of the animal organism for the synthesis of hippuric acid and consequent disposition of ingested benzoic acid. It has been shown that the combining power of glycine is not limited to that preformed, or which may be split off in the ordinary metabolism, but that in addition the potential glycine of other amino groups is also available.

It may be urged that this diversion of potential glycine from more complex acids is in itself an abnormal action, and therefore objectionable. This is possibly true, and would have weight, if we were concerned with the question of ingesting daily 5 grams or more of benzoic acid. But the amounts to be practically considered are so far below this that the question of breaking down extra protein does not come to the front at all.

What amounts of benzoic acid are actually in question here? Practically below 500 milligrams daily, if we consider the ordinary solid or semi-solid foods, or below a gram a day, if we consider certain beverages sometimes treated with benzoate. These are probably extreme figures, as for the great majority of food substances benzoate is not used or in any sense required. What then is the physiological behavior of these small amounts of benzoic acid which

<sup>4</sup> Hofmeister's *Beitraege*, 7: 204.

<sup>5</sup> Jaffe *Festschrift*, Braunschweig, 1901.

<sup>6</sup> *Munch. Med. Wochenschr.*, 52: 2168; *Biochem. Zeitschr.*, 6: 502 and 523.

<sup>7</sup> *Schmid. Arch.*, 58: 397.

have practical significance? Several lines of enquiry may be followed to find an answer to this question, three of which are comparatively direct: (a) the fate in the body; (b) the action on digestive ferments; (c) the action with reference to general health and metabolism.

(a) With reference to the relations under (a) we have already sufficient information. Small amounts of benzoic acid are completely united with glycine, and for 500 milligrams 307.5 milligrams of the latter are required, an amount far within the liberation from the ordinary protein metabolism. In the cases of infants or invalids with lower metabolism the possible benzoate ingestion is naturally far below this, and there would doubtless be always, even in such extreme cases, a sufficient glycine content for combination.

With no benzoic acid ingested the larger part of the glycine would probably go to form urea and other products by oxidation. With the benzoic acid we have the synthesis of hippuric acid. Unfortunately, we have no reliable means of comparing the magnitude of or the difficulty in the enzymic work in the two cases. In certain quarters much has been said about the over-burdening of the kidneys with this work of synthesis. As a matter of fact there is no warrant whatever in the assumption that the tax on the organism is any greater in this case than in the other, and those who make the assumption probably overlook the fact that the hippuric-acid synthesis in the human body is normal and constant. Because of a lack of delicacy in the methods employed for the determination of hippuric acid the quantity of this substance excreted daily has usually been greatly underestimated, or neglected entirely.

(b) The behavior of benzoic acid toward

digestive ferments has been the subject of several investigations. In this direction the action on diastases, pancreatin, pepsin, rennin and the lipases has been studied. A number of such studies have been carried out in my own laboratory, with the general result that while there is naturally an inhibition of digestive activity with certain concentrations of benzoic acid, with those concentrations which have practical importance in the present enquiry the inhibition is very slight or does not appear at all.

In the case of the digestion of starches there is indeed a distinct acceleration in the rate of digestion, as is caused by a number of neutral salts and acids of low concentration. This is true not only of digestions by means of malt infusions, but also in the case of taka-diastase and a number of the pancreatic diastase preparations in general use in this country. Similar results were reported some years ago by *Leffmann*.<sup>8</sup>

While 0.1 per cent. of sodium benzoate added to egg albumin mixture, such as is used in the official pepsin tests, distinctly retards the rate of digestion, this is not the case with one fifth of this concentration, which is probably above the limit ever found in the stomach after the ingestion of benzoated foods. This relation has been observed in a number of mixtures of fibrin as well as egg albumin, and with a variety of pepsin preparations. Analogous results have been reported by *Gerlach* in his lengthy study of the benzoate question.<sup>9</sup>

Very weak concentrations of either benzoate or benzoic acid have no influence on the rennin coagulation of milk, but with an increase in the concentration there is a gradual inhibition. Our results in this

<sup>8</sup> *Jour. Frank. Inst.*, 147: 1899, p. 97.

<sup>9</sup> *Wiesbaden*, 1909.

respect are not essentially different from those of Weitzel.<sup>10</sup> In the clinical feeding of infants sodium benzoate has been frequently added to milk.

According to Amberg and Loevenhart<sup>11</sup> the activity of lipase, as measured by the splitting of ethyl butyrate, is not diminished by the presence of 0.1 per cent. of sodium benzoate. Dakin, working in Herter's laboratory, has made a careful re-determination of many of the digestive constants in presence of benzoate.<sup>12</sup>

(c) We now come to the most important part of the subject, the behavior of benzoic acid with reference to general health and metabolism. At the time when this substance was extensively used in medical practise, that is, from 1875 to 1880, it was recognized by some physiologists that large doses were followed by increased elimination of nitrogen, which, it was assumed, must come from the breaking down of body proteins. E. Salkowski, especially, from experiments on dogs,<sup>13</sup> concluded that high doses might occasion a considerable loss in man. But in the dog experiments the ingested benzoate amounted in the mean to about one third of a gram per kilogram of body weight, which proportion if applied to a man of 50 kilograms weight would call for nearly 17 grams of benzoate, or 25 grams for a man of 75 kilograms weight. Somewhat similar observations were made by other physiologists, but on the other hand the reports from clinical practise failed to show any such losses. To follow these discrepant observations farther is not necessary in this place, as the question of the increased nitrogen excretion has been pretty fully handled in the investigations

of Magnus-Levy,<sup>14</sup> Ringer, and Epstein and Bookman,<sup>15</sup> and others already referred to.

But these early reports have had one very important effect, which must be recalled here. They left the impression that the ingestion of sodium benzoate is in general followed by increased protein metabolism, tissue metabolism possibly, an undesirable result, and this statement is frequently repeated as applicable to all doses of benzoate. A number of lengthy metabolism experiments have shown that for ordinary ingestions of benzoate this increased protein metabolism does not occur. In the last few years the results of several such investigations have been published. One of these investigations was conducted under the auspices of the Bureau of Chemistry of the United States Department of Agriculture, and from it the conclusion was drawn that small doses of benzoic acid or benzoates exert a harmful action on man, a slight loss in weight being affirmed in some cases. It is not my purpose to criticize this work here beyond saying that the published data do not seem to warrant the conclusions drawn, which opinion is shared in a lengthy review of the work by K. B. Lehmann, recently published.<sup>16</sup>

I wish to speak more particularly of the results of the extended studies carried out by Chittenden, Herter and myself, as members of a commission appointed by the Secretary of Agriculture to investigate the question anew.<sup>17</sup> In Herter's work four men were observed through periods of four months, while in the investigations of Chittenden and myself six men on a definite

<sup>10</sup> *Arbeiten aus dem kais. Gesundheitsamt*, 19: 1902.

<sup>11</sup> *Jour. Biol. Chem.*, 4: 1908.

<sup>12</sup> Herter, *Jour. Am. Med. Assoc.*, 54: 1774.

<sup>13</sup> *Virchow's Archiv*, 78.

<sup>14</sup> *Loc. cit.*

<sup>15</sup> *Jour. Biolog. Chem.*, 10.

<sup>16</sup> *Chemiker Zeitung*, November 28, 1911.

<sup>17</sup> Report No. 88, U. S. Department of Agriculture, 1909.

diet containing sodium benzoate were observed through a period of four months.

These studies covered lengthy observations on the general metabolism of the men, the qualitative changes in the urine, the effects on the blood, effects on the intestinal flora, and daily clinical observations on the weight and general condition of the men. Under the head of metabolism determinations were made of the nitrogen balance and utilization, the distribution of nitrogen, the distribution of sulphur and the utilization of fat. From the data of Chittenden and myself, which were fuller in detail than those of our colleague, certain facts are clearly shown. In Chittenden's series of experiments the doses of benzoate were administered as follows:

	Days	
Fore period .....	14	no benzoate
Low benzoate period .....	62	300 mg. daily
After period .....	10	no benzoate
Medium benzoate period ..	7	600 mg. daily
First high benzoate period .	7	1,000 mg. daily
Second high benzoate period	7	2,000 mg. daily
Third high benzoate period	7	4,000 mg. daily
After period .....	10	no benzoate
Total .....	124	71.8 grams

This is an average dosage of 718 milligrams daily, for dosage periods. In my series of experiments the amounts were as follows:

	Days	
Fore period .....	25	no benzoate
Low benzoate period .....	60	300 mg. daily
Medium benzoate period ..	14	600 mg. daily
High benzoate period .....	18	1,000 mg. daily
After period .....	7	no benzoate
Total .....	124	44.4 grams

This is equivalent to an average dosage of nearly 483 milligrams daily for the dosage periods. In either case the dosage more than covers the practical consumption and is doubtless better adapted to throw light on the subject than are the excessive doses previously given. Larger

ingestions of benzoate are no more suited to prove its practical physiological action than would 150 grams of sodium chloride, kilograms of sugar or half liters of vinegar daily be suitable for these substances. With such large ingestions even the common food substances or condiments might be made to appear highly injurious.

Time will not permit me to go into details with reference to all these experiments. It is sufficient to say that no effects whatever were observed which pointed to a modification of the nitrogen or fat utilization, the nitrogen balance or distribution, the sulphur metabolism, the body weight or the hemoglobin content and red and white counts in the blood. The order of nitrogen distribution remained always the same in the period averages, and it was only when doses of 4 grams of benzoate daily were given that Chittenden noticed a slight, but to be expected, percentage decrease in the urea excretion.

*Qualitative Changes in the Urine.*—In all of our work frequent examinations were made for the appearance of sugar or other reducing bodies, traces of albumin, casts, aromatic oxyacids, or other things which might indicate a change in the nature of the excreted bodies. There was never any indication of an alteration in this direction. The occasional appearance of a trace of albumin or of a hyaline cast was no more frequent in the dosage periods than in the fore periods, and was without practical significance.

During the progress of the work frequent determinations were made of the so-called normal reduction of the urine of the men working in my laboratory, by means of a delicate ammoniacal copper solution. No definite changes were noted which could be connected in any way with the benzoate. After the conclusion of the 124 days of

regular experimentation two of the men in my group who had followed the regular routine continued for seven days longer, with higher dosage. They began with 5 grams a day and finished with 10 grams, the average being 7.5 grams daily. With this large dosage there was no reduction which could be noticed with Fehling solution, and nothing which was outside the normal limits for the ammoniacal solution, although there appeared to be a slight increase from the former figures. Other changes were absent. A third man who had not been a member of the experimental squad, but who had followed the same diet routine, took doses beginning with 5 grams and ending with 7.5 grams on the seventh day. No abnormal behavior of any description was noted in his excretion or general condition. In this case it could not be urged that the man had become accustomed to large doses through gradually increasing small doses.

*Temperature, Pulse, Respiration.*—All these factors were systematically noted from day to day for each man. Absolutely no variations from the normal were observed which might in any way be attributed to or connected with the dosage of benzoate.

*Conclusions.*—From all these observations the conclusion was drawn that in the dosage administered, which is large enough for practical purposes, sodium benzoate exercises no recognizable physiological action on the human organism, beyond the slight increase in hippuric acid excretion, a change which is often exceeded after hearty meals of certain berries and fruits which are frequently consumed in quantity. I have recited the facts in some detail because of the long-continued and persistent attempts to create the impression, especially in this country, that sodium

benzoate exerts a toxic action, sufficiently marked to warrant its exclusion from use with foods.

*Gerlach's Studies.*—Attention must be called here to an elaborate investigation carried out by Dr. Gerlach, of Wiesbaden, on the effects of sodium benzoate as used in the food industries. These experiments were continued through a long period and appear to have been conducted with great care. From the numerous clinical and metabolism observations made Dr. Gerlach draws the conclusion that sodium benzoate causes no changes in the body which may be considered as harmful, or which may be taken as pointing to departure from the normal in any direction.<sup>18</sup>

#### COPPER SALTS

It has long been a popular notion that copper salts are decidedly toxic and the older medical literature contains many references to poisoning by verdigris and other combinations of copper. Modern study, however, has shown that these assumed effects were greatly exaggerated. The subject has practical interest now because of the custom, which had its origin in France, apparently, of fixing the color of certain green vegetables by cooking them in the canning process in contact with small amounts of copper sulphate, or other copper salt. The effect depends on the formation of a very stable green compound of copper and a derivative of chlorophyll.

The permissibility of the process has been much debated, especially in France, Germany and Belgium. In France the discussion has been a prolonged one and several scientific commissions have taken part in it. Some of the older commissions made reports finding against the use of

<sup>18</sup> Dr. med. V. Gerlach, "Physiologische Wirkungen der Benzoesaure und des benzoesauren Natron," Wiesbaden, 1909.

copper in this way, but in the more recent studies the results seemed to point to the practical harmlessness of the metal in green peas and beans. In consequence of these French investigations, and later ones in Germany, the use of copper in limited amounts is now tolerated by the food laws of most European countries.

There seems to be no question regarding the physiological action of relatively large amounts of copper salts. They behave as irritant poisons and produce nausea, vomiting, purgation, while the small quantities absorbed exhibit characteristic lesions in the liver, spleen, kidneys and other organs. We are concerned, however, with amounts far below those necessary to cause any such violent symptoms, amounts which could scarcely exceed 15 to 20 milligrams of copper daily in any case, and usually much below this. In the coloring of peas and beans the amount of sulphate used is generally less than 1 gram per kilo, a part only of which becomes fixed in the product, the actual copper content being from 25 to 150 mg. per kilo, ordinarily.

What are the effects of small doses, up to 20 milligrams of copper daily? To answer this question experiments have usually been made with the sulphate or other soluble salt, but it should be recognized that this does not exactly correspond to the practical situation, since in the pea or bean the copper is largely combined as phyllocyanin compound, which in its solubility is very different from the ordinary salts, and is much more stable.

The results of a long series of experiments carried out in my laboratory in the last two years have convinced me that the copper perfectly combined in this chlorophyll derivative is practically without any evident physiological action in amounts up to 12 or 15 milligrams daily, which

amounts would be contained in a weight of the vegetable as large as any one could eat with a relish for more than a short period. There appears to be no effect on body weight, nitrogen metabolism, blood factors or qualitative or microscopic blood findings. Nausea is not produced. But the case is somewhat different when we turn to small doses of copper salts given in tea, coffee, milk or beer. Here in time we notice some effect, especially in causing nausea and digestive disturbances, and also in some cases a slight modification of the nitrogen partition and some of the blood factors.

In young vegetables with high chlorophyll content the copper sulphate used in small amount appears to be very perfectly combined. This compound is remarkably stable and resists the action of the digestive ferments to a degree which prevents any great absorption of the copper. In the case of the green pea especially the chlorophyll is largely in the hulls, and these, still green with their copper compound, may pass through the alimentary tract and be found in the feces but little changed. This copper-chlorophyll complex is but slowly broken up by hydrogen sulphide or ammonium sulphide.

In older vegetables, however, where the chlorophyll has become considerably destroyed this copper compound can not be formed to the same extent and the copper added in the canning operation goes into a union with proteins which is easily broken down. In this case the copper acts much as it does in the ordinary inorganic salts. In experiments I have found it possible to add 250 to 300 milligrams of copper per kilo to old green peas, and others have reported still higher additions. Much of this copper may be separated easily by dilute hydrochloric acid.

The fact that the non-ionic copper in the phylloeyanate is practically inert physiologically has been noticed by others. Reference here may be made to the work of Tschirsch,<sup>19</sup> Spiro<sup>20</sup> and Brandl.<sup>21</sup> These writers agree that other compounds of copper have a much more marked effect. From these other combinations, as well as from imperfectly coppered vegetables, the metal may reach the liver and other organs and in time produce a marked effect. In a series of experiments by Chittenden this absorption has been clearly shown. As long as it is not practically possible to limit the use of copper in greening to the youngest vegetables only, and in a specified small amount, it would seem that it might be well to prohibit its use altogether in foods, where, indeed, it serves no useful purpose beyond imparting a bright green color.

#### SULPHUROUS ACID

Sulphurous acid is used in two essentially different ways in the treatment of food products. First, in the free state or the oxide, and secondly, as a salt, usually sodium sulphite, but sometimes the bisulphite. Some years ago there was for a time a limited application of the true hyposulphite, but this seems to have been abandoned. Sulphurous acid found its first uses in this connection in the protection of must before fermentation, and in the racking off or transfer of wines from one vat to another, or just before bottling. These uses are still in vogue, and other uses have been introduced, especially in the clarification of cane juices before boiling down for sugar, and in the treatment of certain

fruits in the sun-drying process. Within comparatively recent times the application of sodium sulphite in some of the minor meat industries and in the canning of certain vegetables was introduced.

It will be seen at a glance that we have here two rather distinct conditions. In the application of the sulphurous acid in the sugar, wine and fruit industries there is finally a pretty complete combination of the product with the sugars to form the aldehyde compounds, from which the sulphite is gradually oxidized. These carbohydrate-containing substances hold also certain organic salts, the acids of which are in part displaced by the sulphurous acid. The protein and fatty substances of meats, however, are in themselves inert toward sodium sulphite, and the latter remains unmodified or combined. The fats, in addition, protect the sulphite from rapid oxidation. Among food chemists there seems to be a practical recognition of this distinction in the active condition of the two classes of sulphured products, and the question of permissibility of use has been advanced generally with reference to the sulphites, rather than as concerns the carbohydrate combinations.

As observed with relatively large ingestions all these products exert, of course, a somewhat toxic action, and the toxicity of the carbohydrate combinations seems to run parallel with their rates of dissociation as aldehyde compounds. For the pure aldehydes the rate is rather rapid in the glucose compound, as the lengthy investigations carried out by Rost and Franz and by Kerp have shown.<sup>22</sup> But in their experiments the rate of dissociation of the glucose aldehyde compound is undoubtedly far greater than would be the case in the commercial combinations of fruits and

<sup>19</sup> "Das Kupfer vom Standpunkte der gerichtlichen Chemie, Toxikologie und Hygiene," Stuttgart, 1893.

<sup>20</sup> *Muench. Med. Wochenschr.*, 56: 1, 1070.

<sup>21</sup> *Arb. aus dem kais. Gesundheitsamt*, 13: 104, 1897.

<sup>22</sup> *Arb. aus dem kais. Gesundheitsamt*, 21: 1904.

syrups, for example, where there is always a great protecting excess of the sugar present. In most of the experiments carried out to test the pharmacological action the dosage of the sulphur compound has been so relatively large as to render difficult a conclusion regarding the behavior of small doses, or those which have practical importance. This is especially true of the experiments of Kionka frequently quoted.<sup>23</sup>

In Lehmann's experiments on dogs and cats, with doses running up to 37.5 and 62 milligrams of sulphurous oxide (150 to 250 milligrams of sulphite) daily, and extending through about 200 days, no definite harmful effects were seen. Lehmann considered these doses relatively large.<sup>24</sup>

I can refer but briefly to the work of two recent French commissions which have studied the behavior of sulphurous acid in wine, with respect to the health of the consumer. As a result of these investigations an official announcement was made about a year ago in France, advancing the allowable content of sulphurous oxide in wine from 350 to 450 milligrams per liter, of which not over 100 milligrams may be in the free state. I have not heard that this tentative standard has been modified.

This whole question is now under review by the commission appointed by the Secretary of Agriculture of this country, but the lengthy investigations undertaken have not yet been brought to a conclusion, and can not, therefore, be discussed here.

JOHN H. LONG

#### THE THOMAS PENNANT COLLECTION

SINCE the death of Gilbert White's correspondent, Thomas Pennant (1726-1798), the author of "British Zoology," "A Tour in Scotland, Wales and Ireland," and other important works, the collections made by him

have remained almost as he left them, at Downing Hall, Holywell, Flintshire. This estate, with the collections, was inherited by a former Countess of Denbigh, and the present owner, the Earl of Denbigh, C.V.O., being about to dispose of it, has presented the whole of the Pennant Collection to the trustees of the British Museum. Accompanying the Collection are several volumes of a manuscript catalogue in which the specimens were, for the most part, entered and numbered. A fairly large proportion of the specimens still bear numbers corresponding with those in the Catalogue, a very fortunate circumstance, since most of the labels that have been preserved had become dissociated from the specimens to which they referred. The Catalogue is accompanied by letters and lists from several of Pennant's distinguished correspondents. Among the 140 birds are the only two known specimens of the extinct British race of capercaillie, as well as the originals of many birds figured in the "British Zoology" (1766). There are also a few mammals, fishes and crustaceans. The recent shells include 16 type-specimens and 70 figured specimens, all described in the "British Zoology." The fossils run to more than 1,000 specimens and include many from foreign localities presented by the Italian naturalist, Allioni, and others. Three of the British Silurian corals were described by Pennant in 1757, and a mammoth tooth from Flintshire was referred to by him in 1771. Of minerals there are about 860 specimens, of which 340 still retain their original labels. Pennant appears to have begun this section of his collection when he visited the Rev. William Borlase, author of "The Natural History of Cornwall," and from him he received specimens from time to time. Other donors were Bishop E. L. Pontoppiden, author of "The Natural History of Norway," and Emanuel Mendes da Costa, author of "The Natural History of Fossils" (1757). Among the Welsh minerals the most important are those from Flintshire which formed the basis for the description of Flintshire minerals published in "The Tour in Wales" (1778). Additions to

<sup>23</sup> *Arch. Hygiene*, 22: 1896.

<sup>24</sup> *Arch. Hygiene*, 66: 303, 1909.

the mineral series were also made by David Pennant, the son of Thomas. Interesting portions of the collection have already been placed on exhibition at the Natural History Museum; but every specimen is to be carefully preserved, and it may be hoped that in course of time the Museum experts will be able to identify yet other specimens of historical importance.

Thomas Pennant was one of the best known naturalists of his day. At an early age he was in correspondence with Linnaeus. Buffon, whom he visited in Burgundy, utilized the "History of Quadrupeds." Cuvier, in the "Biographie Universelle," spoke of that work as "encore indispensable," and further accorded high praise to the "Arctic Zoology."

#### THE POPULATION OF NEW YORK STATE

THE composition and characteristics of the population of New York, as reported at the Thirteenth Decennial Census, are given in an advance bulletin soon to be issued by the Bureau of Census, Department of Commerce and Labor. Of the total population of New York, 3,230,325, or 35.4 per cent., are native whites of native parentage; 3,007,248, or 33 per cent., are native whites of foreign or mixed parentage; 2,729,272, or 29.9 per cent., are foreign-born whites; and 134,191, or 1.5 per cent., are negroes. The corresponding percentages in 1900 were 39.2, 33.2, 26 and 1.4, respectively, the proportion of foreign-born whites having increased during the decade. In 35 of the 61 counties the percentage of foreign-born whites is less than 15; in 18 it is between 15 and 25; in 6 it is between 25 and 35, and in 2, New York and Kings, it is 35 or over. Of the 2,762,522 inhabitants of New York County, 45.4 per cent. are foreign-born whites and only 15.8 per cent. are native whites of native parentage. In 23 counties the percentage of native whites of foreign or mixed parentage exceeds 25, being 42.6 in Queens, 41.5 in Erie, and 40.6 in Kings. Of the urban population, 27.2 per cent. are native whites of native parentage; of the rural, 66.1 per cent. The corresponding proportions for native whites of foreign or mixed parentage are 36.5 and 19.9

per cent. respectively. The percentage of foreign-born whites is 34.5 in the urban population and 12.8 in the rural.

In the total population of the state there are 4,584,597 males and 4,529,017 females, or 101.2 males to 100 females. In 1900 the ratio was 98.9 to 100. Among native whites the ratio is 97.5 to 100, and among foreign-born whites 110.5 to 100.

Of the total native population—that is, population born in the United States—88.7 per cent. were born in New York and 11.3 per cent. outside the state; of the native white population, 10.4 per cent. were born outside the state, and of the native negro, 59 per cent. Persons born outside the state constitute a larger proportion of the native population in urban than in rural communities.

Of the foreign-born white population of New York, persons born in Russia represent 20.5 per cent.; Italy, 17.3; Germany, 16; Ireland, 13.5; Austria, 9; England, 5.4; Canada, 4.5; Hungary, 3.5; Sweden, 2; all other countries, 8.4. Of the total white stock of foreign origin, which includes persons born abroad and also natives having one or both parents born abroad, Germany contributed 21.5 per cent.; Ireland, 19; Russia, 14.8; Italy, 12.9; Austria, 6.7; England, 6; Canada, 4.7; Hungary, 2.5; Scotland, 1.6; Sweden, 1.6 per cent.

Of the total population, 9.9 per cent. are under 5 years of age, 17.4 per cent. from 5 to 14 years, inclusive, 19.5 per cent. from 15 to 24, 32.5 per cent. from 25 to 44, and 20.6 per cent. 45 years of age and over. The foreign-born white population comprises comparatively few children, only 7 per cent. of this class being under 15 years of age, while 73.6 per cent. are 25 years of age and over. Of the native whites of foreign or mixed parentage, 38.3 per cent. are 25 and over, and of the native whites of native parentage, 49 per cent. The urban population shows a larger proportion of persons in the prime of life than the rural and a smaller proportion past middle age. Migration to the city and the influx of foreign immigrants explains this, at least in part. Of the urban population, 33.6 per cent. are from 25 to 44 years of age, inclusive, and

of the rural population, 28.3 per cent., while the percentages 45 years and over are 18.3 and 28.7, respectively. The large number of children in families of foreign origin may account for the fact that the proportion of children under 5 is greater in the urban population than in the rural.

The Census Bureau classifies as illiterate any person 10 years of age or over who is unable to write, regardless of ability to read. There are 406,020 illiterates in the state, representing 5.5 per cent. of the total population 10 years of age and over, the percentage being the same as in 1900. The percentage of illiteracy is 13.7 among foreign-born whites, 5 among negroes, and 0.8 among native whites. For all classes combined, the percentage of illiterates is 5.9 in urban communities and 3.9 in rural, but for each class separately the rural percentage exceeds the urban. For persons from 10 to 20 years of age, inclusive, whose literacy depends largely upon present school facilities and school attendance, the percentage of illiteracy is 2.1.

In the population 15 years of age and over 39.8 per cent. of the males are single and 33.7 per cent. of the females. The percentage married is 55.2 for males and 54.5 for females, and the percentage widowed is 4.4 and 11.3 respectively.

#### SCIENTIFIC NOTES AND NEWS

THE council of the British Association for the Advancement of Science has nominated Sir Oliver Lodge to be president for the Birmingham meeting in place of the late Sir William White.

A PORTRAIT of Sir William Turner, K.C.B., principal and vice-chancellor of Edinburgh University and professor of anatomy from 1867 to 1903, has been presented to the university. The portrait is the work of Sir James Guthrie. The ceremony took place in the library of the old university, Mr. Balfour, chancellor of the university, presiding. Sir Robert Finlay, K.C., M.P., made the presentation and Mr. Balfour accepted the portrait on behalf of the university.

DR. E. W. HILGARD, emeritus professor of agriculture at the University of California, is recovering from severe injuries received a few weeks ago, when a flight of steps which he was ascending gave way, throwing him to the floor. The broken bones are uniting and it is hoped that he will soon be able to resume his writing, which was interrupted by the accident.

AT the ceremonies connected with the opening of the Phipps Psychiatric Clinic of the Johns Hopkins University Hospital, beginning on April 16, addresses will be given by Sir William Osler and Professor William McDougall, of Oxford; Frederick W. Mott, F.R.S., of London; Professor Heilbronner, of Utrecht; Professor Bleuler, of Zurich, and Professor Orovino Rossi, of Italy.

ON the nomination of the council of the University of Paris, M. Jean Perrin, professor of physical chemistry in the University of Paris, has been appointed visiting French professor at Columbia University for 1913-14.

SIR CECIL H. SMITH, director of the Victoria and Albert Museum, and Dr. E. H. Starling, F.R.S., professor of physiology in the University of London, have been elected members of the Athenæum Club, London, under the rule which empowers the annual election of three persons "of distinguished eminence in science, literature, the arts, or for public service."

AT the dinner of the Chicago Medical Society on February 26 Dr. Abraham Jacobi, New York City, and Dr. Edward Martin, Philadelphia, were the guests of honor.

A RECEPTION was given by the Manhattan Medical Society on February 28 to Dr. Jacques Loeb, of the Rockefeller Institute, at which he spoke on "Some Recent Experiments in Artificial Parthenogenesis."

MR. JOHN J. SCHOONHOVEN, president of the department of zoology of the Brooklyn Institute, has been made a fellow of the institute.

THE REV. A. H. COOKE, known for his work on molluscs, has succeeded Mr. R. Bullen Newton as president of the Malacological Society of London.

MR. FRANK ARMITAGE POTTS, M.A., fellow of Trinity Hall, Cambridge, has been elected to the Balfour studentship.

MR. T. LL. HUMBERSTONE, B.Sc., has been appointed to the Mitchell studentship of the University of London. The studentship, which is of the value of £100, is for the study of some definite feature of business or industrial organization at home or abroad. Mr. Humberstone proposes to investigate the scheme of industrial fellowship in the Universities of Pittsburgh and Kansas under which research work in applied science is promoted with funds provided by, and to some extent under the supervision of, industrial and commercial organizations.

PROFESSOR WILLIAM MCPHERSON, dean of the graduate school and professor of chemistry at the Ohio State University, has been granted leave of absence for the second semester of the current year. He sailed on March 1 for Germany, where he will spend the next six months in research work in chemistry.

MR. LUTHER E. WIDEN, of the University of Iowa, will accompany Mr. Villjalmar Stefansson on his expedition and will make psychological measurements on the Esquimaux.

PREPARATIONS are being made for the despatch of an official French expedition to Franz Josef Land under M. Jules de Payer, son of the Austrian Captain de Payer, who commanded the Austrian expedition that discovered Franz Josef Land in 1873.

MR. ANDERS K. ANGSTRÖM, son of the distinguished Swedish physicist, and now a student at Cornell University, will have charge of a scientific expedition to Mt. Whitney to continue work on the radiation of the sun under the Smithsonian Institution. Mr. Angström was assistant to Dr. C. G. Abbot, director of the Smithsonian Astrophysical Observatory, in his work in Algeria last summer.

PROFESSOR FRANK SMITH, of the zoological department of the University of Illinois, has been requested by the authorities of the United States National Museum at Washington to take charge of its collection of annelid worms belonging to the group of Oligochaeta.

Professor Smith and his assistants are now at work on the anatomical study and classification of the first installment of material, which includes not only North American forms, but also part of the collection made a few years ago by the Roosevelt expedition to East Africa. The remainder of the material in the possession of the national museum will be sent to Urbana as it is needed.

DR. FELIX KRUEGER, professor of philosophy at the University of Halle and Kaiser Wilhelm professor at Columbia University, lectured on psychological subjects last week at the University of Wisconsin and the University of Illinois.

PROFESSOR W. M. DAVIS, during his recent trip to the middle west, lectured at Oberlin College and the University of Chicago on "Dana's Confirmation of Darwin's Theory of Coral Reefs," and before the Sigma Xi Society of Northwestern University on "Human Response to Geographical Environment"; he also spoke at the Francis W. Parker School, Chicago, on "The Highlands of the Rocky Mountains in Colorado."

THE winter course in highway engineering (February 24 to March 8), given this year for the first time at the Ohio State University, has proved to be popular with the engineers of Ohio who are engaged in highway construction. Contractors, inspectors and county commissioners to the number of sixty enrolled for the course. The Ohio Good Roads Federation cooperated with the university in meeting the expense. The lectures covered many phases of highway construction, maintenance and materials. Among the special lectures were Professor A. H. Blanchard, of Columbia University; A. N. Johnson, state highway engineer of Illinois, and J. J. Voshell, U. S. highway engineer, Washington, D. C.

THE fifth annual meeting of the Illinois Water Supply Association was held at the University of Illinois on March 11 and 12. Members of the association are interested in obtaining and conserving an abundant supply of pure water in the state of Illinois. Special

exhibits are to be placed in the hydraulic and the state water survey laboratories. Among the speakers announced were: Dr. E. O. Jordan, professor of bacteriology, University of Chicago; Dr. W. L. Lewis, professor of chemistry, Northwestern University; Dr. S. A. Forbes, professor of entomology, University of Illinois, and others from these universities, and water supply experts from Chicago, London, England, Charleston, S. C., Cincinnati, Ohio, Washington, D. C., and many other large cities.

DR. E. C. JEFFREY, professor of plant morphology at Harvard University, lectured at the University of Illinois last week on the formation of coal.

DR. ALBERT ERNEST JENKS, professor of anthropology, University of Minnesota, delivered five illustrated lectures on the "Philippine Peoples," in New York City, for the Board of Education during the recent intersemester recess.

ON the evening of March 6, Professor A. W. Goodspeed, of the University of Pennsylvania, lectured before the Franklin Institute on "The Relation of Electricity to Matter."

PROFESSOR GEORGE GRANT MACCURDY, of Yale University, lectured before the Science Club of Amherst and the Massachusetts Agricultural College on the evening of March 3, the lecture being based on his past summer's work in the European prehistoric field.

ON February 28, Dr. L. R. Ingersoll, of the physics department of the University of Wisconsin, gave an address on the "Kerr Effect" before the physics colloquium at the University of Illinois.

DR. JOHN SHAW BILLINGS, director of the New York Public Library since 1896, previously professor of hygiene at the University of Pennsylvania, surgeon and lieutenant colonel in the army, died on March 10, aged seventy-three years.

OSCAR DANA ALLEN, professor of metallurgy and analytical chemistry at Yale University from 1871 to 1887, died on March 5 at his home at Ashford, Wash. He had written on the flora of Mount Tacoma.

PROFESSOR OSCAR OLDBERG, dean emeritus of the Northwestern University School of Pharmacy, for thirty years a member of the committee of revision of the United States Pharmacopœia, died in Pasadena, Cal., on February 27.

DR. ARNOLD HELLER, professor of pathological anatomy at Kiel, has died at the age of seventy-three years.

THE Pagel collection of books on the history of medicine, being the library of the late Professor Julius Pagel, has been given to the medical department of Washington University through the generosity of a friend of the institution. The library contains about 2,500 titles.

A MEETING of the committee appointed to make arrangements for the meeting of the British Association in Birmingham in September was held on March 10, Alderman W. H. Bowater presiding. The Finance Subcommittee reported that promises amounting to £5,493 by 642 local people had been received in answer to the circular sent out to 3,000 persons in January. Sir Oliver Lodge mentioned that the local fund would pay the greater part of the expenses of the meeting, and that the membership subscriptions and general receipts for admission would go into the general funds of the British Association for the assistance of scientific research. Professor Gamble, on behalf of the Halls Committee, said it had been arranged to have the president's address and the evening meeting at Central Hall, while the offices, reception rooms and refreshment rooms would be at the Town Hall and Mason College.

ON the occasion of the seventeenth International Congress at London next August, three prizes will be awarded: The Prize of Moscow, commemorating the twelfth congress, of the value of 5,000 francs, will be awarded for work in medicine and hygiene or for eminent services rendered to suffering humanity; the Prize of the thirteenth Congress of Paris, having a value of 4,000 francs, will be bestowed for original work during the past ten years bearing upon medicine, surgery, obstetrics or the biological sciences in their

application to medical science; and the Prize of Hungary, instituted to commemorate the sixteenth Congress of 3,000 crowns, will be given for a notable piece of work in medical science which has appeared in the interval since the last congress. Nominations of candidates for these prizes are invited before June 1, 1913, and should be sent, together with examples of the work on which the candidacy is based, to the Bureau de la Commission permanente des Congres internationaux de medicine, Hugo de Grootstraat 10, The Hague.

THE Southern Society for Philosophy and Psychology will hold its eighth annual meeting at the Johns Hopkins University, Baltimore, on April 8 and 9.

THE annual meeting of the American Breeders' Association was held at Columbia, South Carolina, in affiliation with the National Corn Exposition, January 24-27, 1913. As usual in recent meetings of this association, the work of the eugenics section was especially prominent. Dr. Charles B. Davenport's evening lecture to the citizens of Columbia on eugenics and the colored race was received with interest. He gave a general view of the difficulties brought about by the blending of the unit characters of two races so radically different. A feature of the work of the plant section was a visit to the state experiment station booths at the National Corn Exposition, which is really a national farm crops exposition. A plant-breeding expert in each of nearly a dozen states received the association at his booth and with samples at hand told of one or more varieties of corn, wheat, sugar cane, or other crop which had been materially improved by the state experiment station and had come into wide commercial use in the state. In each case the method of breeding used in producing the new variety, the percentage of increase it produced over the varieties it is displacing and the acreage covered throughout the state were given. For example, a variety of sugar cane in Louisiana was said to now occupy half the sugar cane area of that state with a yield of canes ten per cent. above the yields of varieties it displaced and with a percentage

of sugar in these canes ten per cent. above the old averages. Nearly similar increases were shown in varieties of wheat in Minnesota and Washington, varieties of corn in Indiana, Illinois and other states and varieties of cotton in South Carolina and other southern states.

#### UNIVERSITY AND EDUCATIONAL NEWS

By the death in Wallingford, Conn., of Joseph Lyman, Yale University will receive \$650,000. He held the life use of that sum which was willed to the college by his brother, Samuel Lyman, who died in 1910.

BOTH houses of the legislature of the state of Washington recently adopted the biennial budget submitted by the joint appropriations committees. The University of Washington will receive \$1,004,701. The matter of the replacement of the temporary university buildings by adequate modern structures has been submitted to the legislature separately.

THE recently adjourned legislature of West Virginia gave larger appropriations to the state university than in any previous year. Among others was a special appropriation for the medical work to make it possible to follow out the plans outlined by the committee from the Association of American Medical Colleges.

THE Indiana legislature has made an appropriation of \$65,000 for the medical school and hospital of the Indiana University School of Medicine for the first year, and an annual appropriation of \$75,000 thereafter.

FUNDS have been provided at Columbia University to build a laboratory for the study of cancer under the George Crocker research fund. This fund amounts to over one and one half million dollars, and it was provided that the income should be used solely for research work. The laboratory, which will be 100 by 40 feet and three stories high, will be on the block east of Amsterdam Avenue on 116th St.

THE clinical and laboratory building of the Stanford University Medical Department in San Francisco has recently been remodeled at an expense of about \$40,000. This large building was formerly used by Cooper Medical Col-

lege and had in it, besides the Lane Hall, a number of amphitheaters and lecture rooms, and the Lane Medical Library. With the removal of the Lane Medical Library to its new building across the street and with the shifting of laboratories and the rearrangement of the space formerly occupied by Lane Hall, considerable additional space has been gained for the outpatient clinics and laboratories. The lower floor of the building is devoted entirely to the surgical outpatient clinic, the surgical specialties and the history room and drugstore, the second floor to the medical outpatient clinic and the clinics of pediatrics, neurology and dermatology. The three upper floors are devoted to the pathological museum and the laboratories of experimental medicine, pathology, pharmacology and experimental surgery. Reading rooms have been provided for the students in close connection with the clinical laboratory. This laboratory and the outpatient department are separated by only a short corridor from the clinical wards of Lane Hospital so that both in- and outpatient material is equally available for purposes of teaching. The front part of Lane Hall has been converted into a modern amphitheater suitable for demonstrations. About 12,000 patients were received by the outpatient department during the past year with a total number of visits of over 60,000.

A BILL to establish a college of medicine and dentistry at the Ohio State University is now before the state legislature and has passed the senate. If it becomes a law, the Starling Ohio Medical College of Columbus will be transferred to the state and become the basis of the new college.

CAPTAIN C. E. MARSH, U. S. N., has made public the details of the plan for giving a number of college undergraduates an opportunity to take a summer cruise on some of the navy vessels and thus to familiarize themselves with life on board ship and fit themselves to become members of a sort of naval reserve. The college students will be assigned in squads of 20 to each ship, and as far as possible men from the same college will be kept together.

THE Prussian minister of education has announced that fees at Prussian universities for foreign students will be doubled. Russian students will hereafter be required to be graduates of gymnasia. There has been agitation in Germany recently in regard to foreign students, the University of Munich having limited the number to three per cent. There are at present 5,196 foreigners studying at the German universities, of whom 338 are Americans.

THE 126th anniversary of the granting of the first charter by the legislature of Pennsylvania was celebrated by the University of Pittsburgh on Friday, February 28, 1913. The addresses were given by Provost E. F. Smith, University of Pennsylvania, President E. E. Sparks, State College, and President W. H. Crawford, Allegheny College. The honorary degree of doctor of science was conferred upon John Price Jackson, dean of the School of Engineering, State College.

DEAN F. F. WESBROOK, of the medical school of the University of Minnesota, has resigned to accept the presidency of the University of British Columbia. Dr. Westbrook, who is a Canadian, has been largely responsible for the development of the medical school of the University of Minnesota and its recent reorganization.

PROFESSOR FREDERICK H. SYKES, director of the School of Practical Arts in Teachers College, has resigned in order to accept the presidency of the new Connecticut College for Women at New London.

DR. FREDERICK E. BOLTON has been elected dean of the new college of education at the University of Washington. Professor Bolton was called to the University of Washington last year from the University of Iowa, where he was director of the school of education.

THE fact that Professor E. B. Greene resigned his position as dean of the College of Literature and Arts of the University of Illinois when he took leave of absence last year, has been made public. The reason Professor Greene gives for resigning is that he did not desire the administrative work in connection with the office. At the time of the resigna-

tion, Dr. Arthur Hill Daniels, professor of philosophy, was appointed acting dean. Dean Daniels' appointment is to remain effective until something definite shall be done in regard to the proposed combination of the College of Literature and Arts, and the College of Science.

MR. C. SHEARER, M.A., Clare College, Cambridge, has been appointed university lecturer in zoology.

DR. CONSTANTIN CARATHÉODORY, of the Technical Institute at Breslau, has been appointed professor of mathematics at Göttingen as successor to Professor Felix Klein.

### DISCUSSION AND CORRESPONDENCE

#### RELATIVITY IN ELECTROMAGNETIC INDUCTION

IN SCIENCE of January 17, 1913, S. J. Barnett adduces a certain experiment as constituting an *experimentum crucis* showing that complete relativity does not exist in electromagnetic induction. The experiment is certainly an interesting one, but on closer examination does not seem to be so definitely in contradiction to the principle of relativity as may appear at first sight.

For discussion let us consider the following simple form of experiment which illustrates the same principles. Take a cylindrical magnet magnetized longitudinally and symmetrically about its axis, and mount it in the axis of a somewhat larger cylindrical metal tube, with air or other dielectric between insulating one from the other, and forming a cylindrical condenser. Connect the two by a metal brush or cross-connection reaching radially across from the tube to the middle of the magnet. Now if the whole system considered as rigidly connected is spun around its axis of figure there will of course be induction and a difference of potential established between the magnet and the outer tube, and if the brush connection be broken while the system is in rotation, on bringing the whole to rest the condenser, consisting of tube and magnet, will be found charged.

So also when the tube alone is rotated while the magnet is kept at rest, a difference of

potential is established, provided the metal connecting brush rotates with the tube. Or if the magnet is rotated and the tube kept at rest experiment shows the inductive effect to be the same if only the cross-connection rotates with it. And finally if both magnet and tube are kept at rest while the cross-connection alone is rotated about the axis of the system the observed effect is the same.

On the other hand, no inductive action is observed when tube or magnet or both together are rotated so long as the connecting brush is at rest.

The motion of the cross-connection is thus the determining factor, but relative to *what*? Must not any effect that we can observe be due to motion relative to the apparatus and connections by which the inductive action is tested.

Of course the induction may be conceived as due to motion relative to coordinates fixed in the ether or in space, and the effect would then depend on the direction of the axis of the magnet relative to the earth's axis, and the rotational velocity of the earth, and on its translational velocity in space. But even in that case the inductive action which also takes place on the system by which the effect is tested, in consequence of its motion in space, may be expected to be such that no inductive action could be observed except in case of such relative motion as is specified above.

For so long as the cross-connection and the testing apparatus by which the effect is to be observed are at rest relative to each other no change in the magnetic flux through the circuit will be produced by any rotation of the whole system about the axis of the magnet.

It appears therefore that if the testing apparatus rotates about the axis of the magnetic field at the same rate as the cross-connection between magnet and tube, no charge will be found, while if it rotates with an equal angular velocity in the opposite direction the charge found will be twice as great as if it were at rest.

If these statements are in accordance with the experimental facts, as I believe them to be, then such an experiment can afford no infor-

mation touching the motion of the ether in the field around a rotating magnet.

ARTHUR L. KIMBALL

AMHERST COLLEGE,  
January 20, 1913

#### SCIENTIFIC METHOD

TO THE EDITOR OF SCIENCE: Permit me to protest vigorously against the exceedingly narrow conception of scientific method implied in Professor MacDougall's discussion of "neo-vitalism" in your issue of January 17. I am not a defender of neo-vitalism, and have no interest in the controversy between the neo-vitalists and their opponents; but I am interested in keeping the scientific method broad enough to apply to all phases of human experience. It is surely to be deplored that in this age, just when science is expanding to include all human life within its scope, a few scientific men should persist in interpreting scientific method in such a way as to limit its application to purely physical phenomena. If it is true that "natural science rests finally upon the assumption of mechanism [i. e., rigid determination of all processes through the operation of mechanical causes] and excludes all other conceptions," then there can be no scientific treatment of religion, morality or any other phase of the mental and social life of man. Upon this assumption there can only be physical and biological sciences, and we must give up the hope of having mental and social sciences; for the impossibility of demonstrating mechanical causation in the mental and social realms is acknowledged by all careful thinkers and investigators.

Furthermore, the necessity of science assuming the universality of, and the rigid determination by, mechanical causation, is not evident, unless science wishes to transform itself into a system of monistic philosophy. Rather the pragmatic development of science would permit the assumption of one principle of explanation in one realm of phenomena where it works, and of another in another realm, where that works; for science is "a prolongation of common sense." Thus

in the physical sciences no other principle than the mechanistic one is invoked, because mechanical cause and effect will work as a principle of explanation. But in a science like economics, for example, there is little use made of mechanical cause and effect as a principle of explanation because it will *not* work. All modern economics, as is well known, is built upon the conception of "value." Now, is economics a science, or not a science? To me the attempt to explain economic phenomena through mechanics is as absurd as the attempt to explain biologic phenomena through "entelechy." In either case it is the attempt to explain the known through the less known. The case is exactly similar with all the other social sciences. It may be replied that economics and the other social sciences are "sciences," but not "natural sciences." This reply, however, does not meet the issue, because no one can separate the natural sciences from other positive sciences unless the word "natural" be defined to mean the physical.

I am uncertain as to the purpose of Dr. MacDougall's argument, as to whether he wishes to limit greatly the scope of science (as do some philosophers), or to carry through the mechanistic conception as a universal principle of explanation (as do some scientists). In either case the argument practically denies the possibility of positive sciences of our mental and social life. To many people this is, of course, a welcome conclusion. But the whole development of modern science is against this conclusion. The extension of scientific methods to the mental and social realms of phenomena in the nineteenth century, without any use of mechanistic assumptions, was accompanied by as substantial triumphs in those realms as science has had anywhere. Is it not time to acknowledge this? It will not do to say that the assumption in all cases where science has made substantial advances in explaining mental and social phenomena has been that of mechanism; on the contrary, the mechanistic assumption, when brought in at all, has been brought in as a metaphysical "guess" which really explained

nothing. The use of such an assumption in most cases in the social sciences has usually turned out to be an attempt to explain the known in terms of the less known.

In conclusion, it seems to me that science as science may well beware of accepting as yet any universal principle of explanation. It can not accept such until it is demonstrated. The method of science is not, as some philosophers have proclaimed, to build itself up upon some universal assumption. Rather its methods are the pragmatic ones of observation, comparison, testing by experience and measurement. So far as science approaches exactness it is built up by the method of measurement; and many other things than mechanical cause and effect can be measured. It is decidedly premature as yet to say that science will approve any universal principle or method of explanation; and it is decidedly regrettable that any one who works in any of the sciences should, by a narrow definition of scientific method, rule out of the category of scientific works James's "Principles of Psychology" and the whole list of important contributions in the mental and social sciences not based upon the mechanistic assumption.

CHARLES A. ELLWOOD

UNIVERSITY OF MISSOURI,

January 20, 1913

"MORE LITTLE BEASTS"

TO THE EDITOR OF SCIENCE: Under the title of "More Little Beasts of Field and Wood," Mr. William Everett Cram, of Hampton Falls, New Hampshire, has given an account of various animals met by him in his walks through the woods, written in a pleasant fashion suggestive of Thoreau, though without Thoreau's touch of moral epigrams.

It is illustrated by a number of fairly correct wood-cuts.

A novel suggestion, at first sight not at all convincing, is this, that the group of hares and rabbits is not an off-shoot from the rodents, but from the family of cats, a rabbit in the long past being a cat, adapted perforce to a vegetable diet. A good many parallelisms between the cats and the rabbits are suggested,

among others that cat flesh is sometimes substituted for that of rabbits in the inns of Europe.

DAVID STARR JORDAN

SCIENTIFIC BOOKS

*The Horse and its Relatives.* By R. LYDEKER, F.R.S. New York and London, The Macmillan Company. Pp. vi + 286; Pls. XXIV., and 11 text figs. 1912. Price \$2.60 net.

This extremely interesting volume is a companion to that on the ox and its kindred by the same author, and summarizes most admirably our knowledge of the members of the equine race, both living and extinct. In the opening chapter the place of the horse in nature is discussed, together with that of its few surviving relatives. The eight or nine species of horses, five of rhinoceroses and five or six of tapirs contrast strikingly with the great number of artiodactyles still living. The perissodactyles are therefore looked upon as a waning race, but the cause of their diminution in numbers is not yet determined.

In discussing the structure of the horse, especial emphasis is placed upon the high degree of specialization of feet and teeth. In the foot the variable degree of reduction of the splint bones is of interest, the great shire horse of England retaining the entire shaft together with remnants of the first and second phalanges of the lateral toes, all firmly welded together, while the Argentine horses show the greatest diminution of these bones. The longheadedness so characteristic of all horse-like forms is a very ancient character and gives space before the eyes for the development of the wonderful dental battery. The pit-like depression in front of the orbit sometimes seen in modern horses is supposed to have lodged a scent gland, of recognition value, similar to that of the deer. The leg callosities known as "chestnuts" are also decadent skin glands. The long columnar teeth with their complex infolding of enamel are admirably adapted to the harsh siliceous grasses which constitute the principal article of diet. They are much more perfect than in the cud-chewing ruminants, in which the food

is subjected to a second chewing at the creatures' leisure, after having been softened in the stomach. In the horse the mastication must be hurriedly and efficiently done once for all.

The coloration of living horses gives rise to the belief that the Arab stock has been derived from a dappled bay, while in the domestic horses of western Europe, probably sprung from a different ancestral species, the primitive hue is dun, the color of withered grass. The tendency toward either melanism (black), erythrism (redness) or albinism (white) gives rise to the various color modifications. Striping is characteristic of all African wild horses, while those of Asia are more uniform.

The occasional presence of rudimentary paired horn-like processes upon the frontal bone, while never showing a corneous covering, is of interest. They are not vestigial, as no equine ancestors show them, and while Lydekker does not suggest it, may they not be indications of approaching racial old age?

Cope's idea that the horse tribe had two independent centers of development from animals of more primitive type, one in the old world and a second in North America, is rejected for that of Matthew, who assumes that "since the horses are represented by a double evolutionary series, one in Europe, a closer one in North America, their center of dispersal lay far enough north to spread into Europe on one hand, North America on the other, but that the latter was nearer or more accessible; *i. e.*, their center of dispersal was northeastern Asia or Alaska."

The wild tarpan or Przevalski's horse, still living on the steppes of Tartary and Mongolia, is the only true horse other than the domestic breeds which has survived. Historical evidences for wild horses in Europe may refer to feral animals, the ancestors of which had escaped from bondage. Prehistoric records, on the other hand, such as the drawings on the walls of caves, show the existence of a small, big-headed horse strongly suggestive of the tarpan. This is the so-called steppe type of Ewart. Two others are also represented by

bones and teeth in the Pleistocene of England and the continent, one the plateau type of Ewart, a fine-headed, slender-limbed pony, also depicted in paleolithic art; and the forest type, a long, low horse with short, thick cannon bones and broad hoofs. All three of these are probably races of the modern *Equus caballus* and not separate species.

The author next discusses the domestic horses of the British Isles and some foreign breeds, and their probable origin, including the American feral horses. The latter are derived from those introduced by the Spanish conquerors and are of Barb stock.

Among other living equines the Kiang and Onager group come nearest the true horses. They are Asiatic in distribution, while the asses are apparently from the north of Africa. "It has been stated that 'the ass, and with it its name, accompanied the progress of the culture of the vine and olive to the north, not crossing the limits of that culture. In proportion as the ure-ox, the bison, and the elk died out, the long-eared foreign beast became domesticated in Gaul, receiving various names, and living in the customs, jokes, proverbs, and fables of the people. Germany, however, proved too cold for the animal.'" Asses have become feral in South America. Nearly related to the ass is the true zebra of southern and southwestern Africa, which, together with the now extinct quagga and the bontequagga or Burchell's zebra constitutes the distinctively striped horses of the Ethiopian realm. The curious association of zebras, gnus and perhaps a troop of ostriches to fill up the company, is mentioned, the ostriches apprehending danger through the sense of sight, the others through that of smell. The coloring of zebras, the protective value of which has been so vigorously denied by Colonel Roosevelt, is summarized by the statement that "whatever may be the real truth with regard to some of the disputed points, it is certain that when a zebra enters covert, it becomes, owing to its coloring, indistinguishable."

The final chapter summarizes our knowledge of the extinct forerunners of the horse, the records of which have been so well preserved.

Through each of the five stages—Pleistocene, Pliocene, Miocene, Oligocene and Eocene—of the uppermost eras of geological history we can trace a more or less complete gradation from the horses of the present day to primitive, many-toed animals, scarcely larger than foxes, and presenting few of the features which render the horse and its relatives such a remarkable group. Some idea of the immense lapse of time which has taken place during the slow evolution of the Eocene *Hyracotherium* into the modern *Equus* has been thus expressed by Professor H. F. Osborn, whom Lydekker quotes:

The Rocky Mountains, it is true, began their elevation during the close of the Age of Reptiles; they had only attained a height of four or five thousand feet when the Age of Mammals commenced; they continued to rise during the entire period. But consider the map of Europe and Asia at the beginning of Eocene time and realize that the great mountain systems of the Pyrenees, the Alps, and the Himalayas were still unborn, level surfaces in fact, partly washed by the sea. . . . The birth of the Pyrenees was at the beginning of the Oligocene. At this time Switzerland was still a comparatively level plain, and not until the close of the Oligocene did the mighty system of the Swiss Alps begin to rise. Central Asia was even yet a plain and upland, and only during the Miocene did the Himalayas, the noblest existing mountain chain, begin to rise to their present fellowship with the sky. In North America, again, since the close of the Eocene the region of the present Grand Cañon of the Colorado has been elevated 11,000 feet and the river has carved its mighty cañon through the rock to its present maximum depth of 6,500 feet.

Those who have been impressed with a sense of the antiquity of these wonders of the world, and will imagine the vast changes in the history of continental geography and continental life which were involved, will be ready to concede that the Age of Mammals alone represents an almost inconceivable period of time.

RICHARD SWANN LULL

YALE UNIVERSITY

*Electricity and Magnetism for Advanced Students.* By SYDNEY G. STARLING. Longmans, Green & Co. 1912. 583 pages, with 452 figures.

This book is the outcome of a number of years' experience in teaching the subject to senior students in an English municipal technical school, and it is a good book. To quote from the preface, it aims "to give such students an adequate knowledge of the present state of the subject, with due reference to the historical sequence of its development, and to the effect of modern research upon it." Its seventeen chapters are devoted to magnetism, terrestrial magnetism, the electric current (2), electrostatics (2), electrolysis, thermoelectricity, electromagnetics, magnetic properties of materials, varying currents, alternating currents, units, electromagnetic radiation, conduction in gases, radioactivity, and electrons. Instruments and methods of measurement receive a great deal of consideration. Each chapter is provided with a number of examples, mostly taken from London B.Sc. and B. of E. papers.

The book follows for the most part conventional lines. Its descriptive matter is clear and full and usually correct. Its mathematical demonstrations are ordinarily sufficiently direct and simple, though it seems to the reviewer that some of them might have been dispensed with and that others, *e. g.*, those pertaining to the Wheatstone and Thomson bridges, would profit by simplification. The calculus is freely used throughout.

As to matters of fact the book is fairly up to date. In many cases, however, important recent contributions receive no mention—such as the use of the methods of electromagnetic induction in terrestrial magnetism, the precise work of Rosa and Dorsey on the ratio of the unit charges, and the brilliant work of Langevin, Weiss and others in the domain of magnetism.

In matters pertaining to fundamental theory the treatment is not always logical and free from looseness. Thus the definitions of electromotive force and potential difference are unsatisfactory; resistivity is defined without reference to the direction of the streamlines; the curl of a vector is defined as its line integral around a closed path; and Gauss's theorem, demonstrated for a homogeneous field only, is assumed without comment to

hold for all fields—an error common to nearly all books on this subject. And many other errors have been noted, most of them pertaining to the theory of instruments.

As in many other books, great use is made of the magnetic shell. In the reviewer's opinion magnets of all types, real or fictitious, but especially the magnetic shell, should be completely abolished from the fundamental parts of electrical theory—as indeed they have already been abolished by some writers. The reviewer must protest also against the author's use of the word *field*, which properly denotes a *region*, to designate field *strength* or field *intensity*; and the use of the word *force* in place of the word *stress* when two forces—both action and reaction—are contemplated. These usages are all too common, and the book under review is no more guilty than many others.

In spite of such defects as have been mentioned it may be stated again that this is a good book. And it should be useful to many students.

S. J. BARNETT

THE OHIO STATE UNIVERSITY

*The Science of Human Behavior: Biological and Psychological Foundations.* By MAURICE PARMELEE, Ph.D. New York, The Macmillan Company. 1913. Pp. xviii + 443. \$2.00 net.

It is the subtitle rather than the main title that indicates the scope of this work, which might perhaps have been better named *Prolegomena to a science of human behavior*. No attempt is made to gather together the rather extensive studies of human behavior already produced by experimental psychology, and indeed the existence of this work is not even recognized, nor are its methods set forth. The author's view is that human behavior must be approached from the biological and physiological side. "Psychical and social phenomena should be reduced as far as possible to biological terms, just as vital phenomena should be reduced as far as possible to chemical and physical terms" (Preface). "To begin the study of behavior from a biological point of view has, I believe, a very

wholesome effect, for it necessitates the use of more or less exact methods of observation which are not always used in psychology and sociology. The use of these methods results in the disappearance of hazy and mystical explanations of human phenomena frequently proposed by writers in these two sciences. These explanations are replaced by more or less exact mechanical explanations" (pp. 2-3). The nature of these mechanical explanations is indicated by the author's method, which seeks to obtain clear concepts of the simpler types of behavior, and then to show how these simpler acts are combined into more complex behavior of a mental and social sort. The method is, therefore, comparative and genetic; and phylogenetic rather than ontogenetic. Tropisms and other reactions of the simplest organisms, reflexes of animals possessing a nervous system, instincts, which are defined as combinations of reflexes integrated by the nervous centers, learning, intelligence, consciousness, society, are successively treated; and some attempt is made to trace the evolutionary process through these increasingly complex modes of behavior. As might be expected, this attempt to trace the phylogenesis of human behavior is not specially successful, on account of the impossibility of selecting a series of animal forms representing the direct line of human descent; and the study is thus, after all, comparative rather than genetic. For example, considerable attention is devoted to the social behavior of insects and of birds, which certainly has no direct bearing on the evolution of human behavior. For the specific purpose of the book, much of this incidental material might well be replaced by something on the growth of behavior in the human individual.

The book is of the Spencerian type, beginning with the characteristics of matter in general, and ending with social evolution. It has required the bringing together of material from various sciences: physics and chemistry, zoology, physiology, psychology, anthropology. One would expect it, accordingly, to be broad rather than notoriously exact; and it is likely to produce the same sort of impression

that is produced by Spencer's work, least satisfactory where the reader knows most about the subjects treated. Certainly under the heads of neurology and psychology, it is somewhat inaccurate and a trifle naïve. The author seems willing almost anywhere to take up a position on questions that are controverted and inherently difficult of decision. Another criticism is that the deductive tendency is more implicitly followed by the author than the nature of his material allows. Once having reached a (perhaps tentative) conclusion on some question, he is satisfied to use this conclusion as the basis of far-reaching deductions. For example, this is his evidence in favor of a richer emotional life in warm-blooded than in cold-blooded animals: "The warm-blooded type developed as a result of the development of the sympathetic nervous system, which regulates the vasomotor system in such a fashion as to keep the body at a uniform temperature by sending blood where more warmth is needed and stimulating the action of the sweat glands where the heat needs to be reduced. I have not the space to discuss the causes for this development here. As we have seen in an earlier chapter, the emotions arise out of the activity of the sympathetic system, so that the development of that system means the development of the emotional nature of these classes of animals. So that the emotions involved in sexual, parental and wider social relationships now begin to play a wider part" (pp. 372-373). It is but fair to say that the author's treatment is much more satisfactory when the broad trend of the book is considered than when particular passages are taken for examination. Certainly it is well to bring emphatically before the reading public the notion that a science of human behavior is possible (and actual, as well, to a much greater degree than this book indicates), and that this science is distinctly a biological science, related to the study of animal behavior, on one side, and on another, to the structure and functions of the nervous system.

## BOTANICAL NOTES

### FIGHTING THE CHESTNUT BLIGHT

ONE of the most interesting contests is now being waged between the trained plant pathologists on the one hand and a parasitic fungus on the other, and thus far it must be admitted that the outcome of the battle is by no means as assured as we could wish it to be. The chestnut tree is found naturally in an area stretching from southern Maine to Georgia and Alabama and extending a greater or less distance east and west of the Appalachian Mountains. A few years ago (1904) a disease of the bark of this tree appeared near New York City, and from this point it has spread northeastward, westward and southeastward as far as Massachusetts, Vermont, Central Pennsylvania, Maryland and Virginia. It has been made out that the disease is due to a Sphaeriaceus fungus known as *Diaporthe parasitica*, the structure of which has been pretty well investigated.

So threatening has this disease become that last February a general conference was held in Harrisburg, Pennsylvania, for the consideration of ways and means for preventing its further spread, the results of which appeared a little later in a thick pamphlet of a little more than two hundred and fifty pages of papers, discussions and proposed programs. Many half-tone reproductions of drawings and photographs add greatly to the value of the publication, which must prove to be most useful to the man who wants to try to save his chestnut trees, as well as to the botanist who wishes to keep in touch with this contest between pathological science and a rapidly spreading, disease-producing fungus. As the pamphlet is a state publication it can no doubt be had by application to the governor, at Harrisburg, Pennsylvania.

### BOTANICAL NOTES

A HANDY little flora of central and northern Europe has been compiled by F. Hermann, and published by Weigel (Leipzig) under the title of "Flora von Deutschland und Finnland sowie von Island und Spitz-

bergen." It covers the area bounded westwardly by Belgium and eastern France, southwardly and easterly by Switzerland, Galicia and central Russia, to the White Sea, Spitzbergen and Iceland. It thus includes Germany, Belgium, Holland, Denmark, Norway, Sweden, more than one half of Russia, besides parts of Austria and France, and the islands mentioned. Yet in spite of the large area included the book contains only 524 small octavo pages. It should serve as a good model for our North American manuals.

MISS FREDERICA DETMERS has published her dissertation for the doctorate, "An Ecological Study of Buckeye Lake," as a contribution to the phytogeography of Ohio, constituting a pamphlet of 138 pages. This artificial lake, a little more than seven miles long, and from a quarter of a mile to a mile and a half in width, was constructed eighty years or more ago on the site of an impassable swamp. Some interesting studies were made by Miss Detmers, and these are recorded in her paper. There is an annotated list of plants collected in and about the lake, and a good bibliography.

THE New Jersey Forest Park Reservation Commission has issued a useful pamphlet entitled "The Planting and Care of Shade Trees" which may interest botanists, and certainly will do so for those who are interested in trees. The second half of the book is devoted to "Insects Injurious to Shade Trees," by the state entomologist, J. B. Smith, and "Diseases of Shade and Forest Trees," by the state plant pathologist, M. T. Cook. Many good "half-tone" reproductions of photographs add much to the value of the report.

ALLIED to the foregoing is the paper on "Cultivation of Native Ornamental Plants," by Miss Eloise Butler, in the October *Minnesota Horticulturist*. In it the author enthusiastically urges the use of a large number of wild plants, listing them under the following heads, Trees, Shrubs, Woody Vines, Herbaceous Vines, Shade Plants, Early Flowering Herbs (chiefly shade plants), Flowering Herbs

that will grow in Full Sun. On reading the paper one is filled with a desire to make a little wild garden in one's back yard.

HERE we may notice briefly Professor Henry Kraemer's "Outlines of Courses in Botany, Microscopy and Pharmacognosy" for pharmacy students. The "first year's work" (botany) as here outlined is one of the best we have seen.

A DOZEN years ago Professor Selby, of the Ohio Agricultural Experiment Station, published a bulletin (No. 121) entitled "A Condensed Handbook of Diseases of Cultivated Plants in Ohio," which proved to be so useful that a demand sprang up for it all over the country. Two years ago he published in pamphlet form a revised and enlarged edition (No. 214) under practically the same title, and now we have a bound book with essentially the same matter as the second edition but with the title "Handbook of Diseases of Cultivated Plants." This also is issued by the Experiment Station, and is numbered as before (214). In its present form it is a handy book of somewhat more than one hundred and fifty pages of text and includes one hundred and six text illustrations. We may hope that in time this may grow into a still more complete handbook of plant diseases, the need of which is suggested by the demand shown for this bulletin.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

#### THE AGE OF *PITHECANTHROPUS ERECTUS*

JUST twenty years ago Dubois startled the scientific world by his announcement of the discovery of the skeletal remains of an ape-man, *Pithecanthropus erectus*, near the hamlet of Trinil in east central Java. The age was supposed to be Pliocene, and recently Dubois has reiterated his belief in the Pliocene age of this unique material, in which he is confirmed by Stremme and others. Discussion of the age of these remains has been the basis for a considerable volume of literature and the recent tendency has been toward considering *Pithecanthropus* younger rather than older. Thus Martin and Elbert assign it to the old

Pleistocene while Volz, Carthaus, etc., consider it middle Pleistocene. The two Selenka expeditions to Java in 1906-07 and 1908 made rather extensive excavations at Trinil and brought back large collections of fossil plants. These have now been described by Schuster,<sup>1</sup> of Munich, and as the results are important the readers of SCIENCE should have their attention called to Schuster's conclusions.

The exposure of the *Pithecanthropus-schichten* at Trinil at the locality where the human remains were found in 1893 is about 25 meters in thickness and consists of interbedded conglomeratic tuffs, lapilli, ash-beds and clays, partially fluvial or lacustrine and probably partly eolian. Plant remains either as leaf-impressions, lignite or petrified wood are scattered throughout the section, occurring most abundantly, however, in stratum No. 6 in the lower half of the section and at the level at which *Pithecanthropus erectus* was found. Eight species of fresh-water gastropods were collected from member No. 4 above the main plant bed, and waterworn bones occur in member No. 5 which is above, and No. 9 which is below, the main plant bed. The main bone stratum, No. 9, contains a meager fauna which is said to show affinities with the Pliocene Siwalik fauna of northern India.

The flora described by Schuster comprises fifty-four species, none of which are extinct, distributed among twenty-two families. The most abundant families are the Moraceæ and Anonaceæ each with eight species, and the Lauraceæ with six species. The geographical distribution of these fifty-four species in the existing flora is somewhat different from what it was at the time of *Pithecanthropus*. Only ten still flourish in the immediate vicinity of Trinil although thirty-two or 62 per cent. are still found on the Island of Java. Twenty-nine or 57 per cent. are mainly Indo-Chinese in the modern flora and one species, *Uvaria zeylanica* of the Anonaceæ, is confined to

Malabar, Ceylon and India. Schuster concludes that this flora is of Pleistocene and not Pliocene age, and there can be no question of the correctness of this conclusion, since all the forms are still existing, while in the upper Pliocene flora of Mogi described by Nathorst from this same general region 40 per cent. of the species are extinct. Moreover none of the Pliocene plants described by Criei from Java are present in the present collection. Schuster considers that this Pleistocene flora indicates an annual rainfall of about 400 cm. and a mean temperature of 64 to 68 degrees Fahrenheit. If these deductions are legitimate they show that temperatures were somewhat lower than present-day Javan temperatures, while the rainfall was somewhat greater than it is at the present time. Schuster considers that this Pleistocene flora flourished during a pluvial period which corresponds to the Mindel or second glacial period of Alpine glaciation according to Penck's nomenclature, and that *Pithecanthropus erectus* is slightly older than *Homo heidelbergensis* discovered in 1907 by Schoetensack at Mauer near Heidelberg, Germany. Just how this exact correlation is reached it is difficult to understand; in fact I hardly see how there can be any reliable data for such a long range correlation. It seems to me that the exact stage in the Pleistocene is undeterminable. According to Schuster's correlation the age is lower middle Pleistocene, although he calls it old Pleistocene. In the temperate zone a fossil flora with no extinct species indicates a late middle or upper Pleistocene age, but very likely this does not apply with equal force to tropical regions where the physical conditions have been more uniform than in the temperate zone.

The three largest of the Sunda Islands—Java, Borneo and Sumatra—are separated from the Indo-Chinese mainland and from each other by shallow seas less than one hundred fathoms in depth and for the most part not deeper than fifty fathoms. These seas date from the submergence in the late Pleistocene. In spite of this fact and the further fact that the mountain axis of Sumatra also

<sup>1</sup> Schuster, "Monographie der fossilen Flora der *Pithecanthropus-Schichten*," *Abh. k. Bayer. Akad. Wiss., math.-physik. Klasse*, 26 Band, 6 Abhandl., 1911.

forms the backbone of Java, the intervening Sunda Strait being only fifteen miles across, the existing flora and fauna of Java are less like those of Sumatra than those of the latter are like those of Borneo. The biota of Java is, on the other hand, much more like that of the Siamese peninsula and northern India, and it is very interesting to find similar and apparently anomalous affinities shown as long ago as the Pleistocene and certainly before the submergence which gave the region its present physical geography.

##### SOME RELATIONS BETWEEN ROOT CHARACTERS, GROUND WATER AND SPECIES DISTRIBUTION

OBSERVATIONS on the root habits of desert shrubs indicate that the root-type of any species may be of importance in limiting the distribution of the species. This has been found to be especially clear in the case of plants having obligate tap roots, which, as a rule, are confined to relatively deep soils. Such shrubs as have a generalized root-system, on the other hand, have a wide local distribution, which may be correlated with the fact that the roots of these plants are capable of a large degree of modification in conformity with the pressure of the soil environment. But the rôle of the superficial type of roots, such as is typical of species with water storage capacity, is not so well defined. It is known that the fleshy cacti, for example, are most highly developed where the rainfall is a periodic one, occurring, perhaps, twice each year, but that these plants occur sparsely where the precipitation takes place once annually. Whatever may be the reason for this limitation, it is noteworthy that the larger mass of absorbing roots of species having a water balance lie within 10 cm. of the surface of the ground. The superficial soil layer is subject to the most intense desiccation, and, hence, carries moisture in sufficient amount for the use of plants for the shortest period only, so that plants depending on this stratum for moisture must either be

short-lived or have the capacity of storing up water against the following period of drought. What the minimum absorption time of fleshy plants is, has probably not been determined, but it is evident, from their distribution, that the amount of available moisture in the superficial soils derived from a single rainy season each year is not sufficient. To put the case in another way, it is apparent that the general and local distribution of the fleshy cacti would be other than it now is, if such plants had another type of root-system, for instance, if there was an obligate deeply penetrating root-system, in place of the superficial one they now have. Such a change, were it possible, would, in the first place, limit the local distribution to flood plains or to other areas having deep soil, and, in the second place, it would permit a wider general distribution. This suggestion makes it evident that the root-soil moisture relation may be an important factor among those which determine the survival of a species.

Such observations as have been made on the root habits of trees indicate that in these large-bodied plants the root character may also be of importance among the factors which operate to influence their distribution.

It is now well established, at least for a portion of the Southwest, that there may be a very intimate relation between the occurrence of certain species of trees and the character of their roots, having regard to the depth at which perennial water may be found. Here trees occur along streamways, while the nearby upland may be treeless. The humidity of the two areas may not be very unlike, nor the rainfall, nor yet the temperature. The great difference, which is often striking, lies mainly in the soil conditions, particularly with regard to the depth to the ground water. On the bottoms the water table lies within reach of the roots of trees, while on the more elevated land it is far below them.

The depth to the level of ground water, or to the soil that is moistened from the water table, is usually not great. In the eastern portion of the United States, in lands of mod-

erate elevation, water can commonly be obtained within 30-40 feet of the surface, while in the valleys the water lies at a depth of 15 feet, or less.<sup>1</sup> In the states of the middle west, as in Kansas and Nebraska, according to various sources, mainly the Geological Survey, the depth to ground water on the flood plains of streams varies from 10 to 40 feet, but the depth on the benches, valley sides and upland is from 60 to several hundred feet. A like condition is to be found in the more arid regions further west, while the more humid regions of the extreme West are similar, as regards depth to the water table, to the humid east. In rough and mountainous regions, the water reservoirs of whatever kind may be regarded as the physical equivalents of the water table of the more level country, and provide such plants, especially the trees, as penetrate to them, or to the soil moistened by them, with a perennial supply of water.

The various physical factors, climatic as well as those pertaining to the soil, which influence the distance to ground water, are, in the main, of significance in the physiological activities of the trees occupying an area. And, in addition to such factors, appropriate temperatures being assumed, the specific responses of trees to the water relation are to be considered. Chief among these are the water-retaining and water-absorbing capacities and adjustments, of which the root-ground water relation must be considered to be of great importance.

The general relations of trees to perennially moist soil, as indicated by the depth of the water table and by the distribution of trees and forests, and taken from a few widely separated regions, may be illustrated by a few examples.

In southern Arizona, in the vicinity of the Desert Laboratory, the distance to the water table, or to perennial ground water, is various. On the bajada, water is to be obtained at a depth of 70 feet, or over, while on the flood plains of the streams it lies from 15 to 35

feet beneath the surface. There is practically no arboreal flora on the bajada, but along the streams, and on their flood plains, occur ash, cottonwood and mesquite, the latter often forming an open forest of trees ranging as high as 40 feet, or more. The mesquite may be taken to illustrate the relation between trees of the vicinity and the depth to perennial water supply.

The mesquite is the most widely distributed tree of the Tucson region, occurring not only on the flood plains of streams, but on the higher bajada as well. The form of the species, however, when growing in such diverse habitats is quite unlike, since apart from the flood plains it assumes the form, not of a tree, but of a shrub. There is a close association between the dual habit of the mesquite as noted and the depth to the water table, which is also shown by a variation in the development of its roots.

The root-system of the mesquite is an extremely variable one. It may penetrate the ground deeply, or it may extend widely and lie not far beneath the surface of the ground, or, again, it may be of rather limited extent and of a generalized character. The first type of root is probably most characteristic of the tree form, and the last of the shrub form of the species, while the second arrangement may be connected either with the tree or the shrub habit. On the flood plain, roots of the mesquite as a tree have been seen to penetrate to a depth of 15-24 feet, or to the level of the water table. Under especially favorable soil conditions, as where it is fairly homogeneous and easily penetrable, the roots may attain a greater depth.

A comparison of the distribution of the tree form of the mesquite with maps which give the water table depths indicate that the species becomes a tree, soil conditions favoring, where the ground water does not lie deeper than 50 feet. On the other hand, where the water table is at a greater distance, or is otherwise not available, the shrub habit is assumed, with characteristic generalized root-system.

<sup>1</sup>Crider and Johnson, "Water Resources of Mississippi," U. S. Geological Survey, Water-Supply and Irrigation Paper No. 159, 1906.

An extension of observations on tree distribution, as related to the depth of perennial water, to regions outside of southern Arizona, gives interesting, if not entirely conclusive, results. A comparison of the depth to ground water of the Coastal Plain of Texas, as given by Taylor,<sup>2</sup> with the tree distribution, as given by Bray,<sup>3</sup> for example, offers important suggestions in the present connection. In general, it may be said, that the stream bottoms of the Coastal Plain support a hardwood forest, which also extends over such upland as has a fairly shallowly placed water table. Such of the deciduous trees as are marked xerophytes, for example, the post oak, occur on dry ridges where pines of various sorts are also to be found, and where the depth to permanent water is considerable. Of these trees, the root habit of the long-leaf pine is known. This species has a long tap root which penetrates to a great depth and which renders the species in a measure independent of surface conditions of soil and moisture. In the more arid southern portions of the Coastal Plain, where the water table lies below 50 feet, chaparral is characteristic of the upland, and, along the streams, where the water table is less deep, forests occur.

Northward from Texas, as well as westward from the Coastal Plain of the state, are to be found conditions analogous to much already noted for southern Arizona and the Coastal Plain. That is, other things being equal, trees and forests, especially deciduous forests, are limited to areas where the depth to the water table is not great. Thus, in Kansas and Nebraska, the deciduous forests are mostly confined to the flood plains of streams, while the adjacent upland is treeless.

As one examines other regions (reference is made more in particular to those that are semi-arid) he finds forests confined to such areas as are underlain by ground water not beyond the attainment by the roots of trees.

<sup>2</sup> U. S. Geological Survey, Water-Supply and Irrigation Paper No. 190, 1907.

<sup>3</sup> U. S. Dept. Agric., Bureau of Forestry, Bull. No. 47, 1904.

Although it is not practicable at present to give in detail the relation of tree roots to the water table in the more humid regions, enough is known to justify the belief that often there is a very intimate relation between the two, according to Bowman.<sup>4</sup> For example, the level of the ground water is said always to be lower in a forested tract. The same writer states that the greater supply of moisture for trees is derived from deeper lying sources, *i. e.*, than which supplies shallowly rooted plants. The roots, also, which supply the moisture, descend to a point a little above the surface of the ground water. If the level of the water table changes greatly, the trees suffer either from lack of moisture, or from poor aeration, according as it is lowered or raised. The variation in depth to the ground water, however, does not affect trees having superficial roots, or at least roots which do not attain it, and such species are well adapted for growth where the water table is high, or the upper soil is shallow. The ecological importance of this is apparent, and may be illustrated by a single example. Rossmässler<sup>5</sup> mentions trees which are characteristic of two habitats, of which one is rough and stony, and the other is underlain by an impervious clay. Oaks and pines form a mixed forest in the first habitat, and of these the oaks at least have deeply penetrating root-systems. In the second habitat there is only *Picea*, since the soil depth prevents such root development as is characteristic of the other species.

An important phase of the study of the relation of roots to the water table lies in observing the range of variation under natural conditions. Specialized roots, such, for example, as were mentioned at the beginning of this note, are, generally speaking, not capable of great variation. Hence, plants with this character of a root-system, and for this reason only, may have sharp bounds placed on their distribution. On the other hand, generalized root-systems are often variable to a high degree, and, corresponding to this fact,

<sup>4</sup> "Forest Physiography," p. 42, etc., 1911.

<sup>5</sup> "Der Walde," p. 31, 1881.

the species bearing generalized roots may have a relatively wide distribution, occurring in widely different habitats. Cowles<sup>2</sup> gives an interesting example of the relation between root variation and species range. The red maple grows in swamps and also on dry grounds. The root character of the tree on the two habitats is very unlike. In the swamps the tap root is not largely developed, but the laterals are prominent, while in the dry situation the reverse is the case, the tap root being the leading characteristic of the root-system.

The problems which deal with the presence of trees are primarily physiological and have mainly to do with the absorption and conservation of water. Each of these capacities varies with the species. Of the root relations that of the root-water table is of prime importance, owing to the fact that the soil horizon, tapped by the roots of trees, derives, by capillarity, from the level of ground water, its perennial supply of moisture. In the semi-arid regions probably the roots of most trees attain to the perennially moist soil, sometimes to the water table itself, at least for a portion of the year, and, in the more humid regions, the roots frequently do so. In both regions, certainly in the former, wherever such is not the case, a variety of factors, which need not be discussed in this place, are of greater importance in the survival of the species than the water table depth, although the character of the root-systems may still be of much, possibly of definitive, importance.

W. A. CANNON

DESERT LABORATORY

#### INORGANIC COLLOIDS AND PROTOPLASM<sup>1</sup>

BREDIG<sup>2</sup> has shown that inorganic colloidal solutions, such as silver, platinum and gold, may act as catalyzers in certain chemical re-

actions, such as the reduction of hydrogen peroxide to water, and while chemists have studied the problem of the action of catalyzers from this standpoint, biologists have signally avoided attempts<sup>3</sup> to determine whether the activities of the enzymes of the organism can be imitated by these inorganic catalyzers. It must be remembered in any such examination that, as Ostwald<sup>4</sup> has demonstrated, along with others, enzymes of any nature are incapable of instigating a reaction, but their function is solely that of modifying the Guldberg-Waage mass action equation for a given instance, either accelerating or retarding a reaction already in progress. Therefore, we should not expect to find a striking modification of the actions or of the structure of any organism, if any effect were obtained by the application of inorganic "enzymes."

In a series of experiments, I attempted to determine whether colloidal platinum and a colloidal gutta percha<sup>5</sup> gave evidence of any effect upon simple organisms, such as protozoa and single-celled plants. Platinum black was obtained by the use of the house current, reduced to about 70 volts, passing it through a lamp-board, the current delivered to water which had been glass-distilled, the electrodes being of platinum, according to the Bredig method.<sup>6</sup> In order to be certain that the solution was desirable for experimentation, it was examined over a Zeiss dark-ground con-

<sup>1</sup> Benj. Moore (in "Recent Advances in Physiology and Biochemistry," L. Hill, Edt. London: Edward Arnold, 1908; Chapter 4, p. 122) mentioned having performed injection experiments with platinum sol on animals, but he gives no details; he obtained negative results. Autolysis has been shown to become accelerated under the influence of colloidal metals. (See Ascoli and Izar, *Biochem. Zeitschr.*, Bde. 5, 7, 10, 14 and 17; also Doerr, same journal, Bd. 7.)

<sup>2</sup> "Über Katalyse," *Vortrag auf d. Ges. d. Naturf. u. Ärzte*, 1901.

<sup>3</sup> Professor Henry A. Perkins, of the Jarvis Physical Laboratories, Trinity College, prepared this solution after the formula which he used in the laboratory of Professor Perrin at the Sorbonne, and I am indebted to him for the kindness.

<sup>3</sup> "Anorganische Fermente," Leipzig, 1901.

denser, but no attempt at ultra-filtration, which might easily have been done by using collodion as Schoep<sup>7</sup> has done, was made, for I was not concerned in these experiments with the size of the particles. The solutions were found to be quite active and little or no deposit of the coagulated platinum ["sponge"] was obtained, which, of course, is not active catalytically to the extent to which platinum black is. I have tried colloidal iron in somewhat similar experiments, but it is assuredly not to be expected that this colloid would give results with living things, on account of its low activity as an inorganic catalyzer. The gutta percha was dissolved in ether and emulsified by water and alcohol, and then the whole mass was dialyzed through fish-bladder for three months to remove the alcohol and ether. It was examined before using, to determine the activity as far as the Brownian movement could be taken as a criterion.

*Paramecium*, *Stentor*, *Blepharisma*, *Euglena*, *Phacus* and diatoms, *Ceratium* and other desmids were used as material, but more exact work was done with *Paramecium* and *Stentor*. One set of experiments consisted in isolating individuals of these species and making drop-cultures of them in a small amount of the colloidal solution; a second series was conducted in salt dishes, where the amount of colloidal solution was about 2 cm<sup>3</sup>. I ran checks with tap-water.

It was to be expected that the platinum solution, at any rate, would prove to be toxic, but this was not the case, for the organisms lived without any suggestion of being in an unwholesome medium; the same was true for the gutta-percha solution. The rate of cell-division was noted, comparing that of the individuals under experimentation with that of the checks. The rate was found to vary in no appreciable manner. One variable may have been introduced, and that was food, but I could not devise any way of eliminating the difficulty. Bacteria were present in all of the solutions and, of course, in the medium of the control experiments. The bacteria were

kept down appreciably by keeping the dishes in strong light, but this did not eliminate them.

From these experiments, which are by no means exhaustive, I conclude that the inorganic catalyzers, such as I have used, are not effective in appreciable manner on protoplasm. It may well be that protozoa are not affected, while other organisms, or portions of other organisms, may be. As an instance where protozoa are not affected by an agent that is markedly effective in inducing cell-division in certain tissues in higher forms, I may mention the power of certain azo-compounds, notably Scharlach R, to cause proliferation of epithelium in mammals, so that they have been introduced into dermatology for treatment of burns on the skin, and it has been noticed that workers in anilin factories<sup>8</sup> show thickenings of the skin caused by contact with the dyes. I have grown *Paramecium* in drop-cultures with granules of Scharlach R, which were seen to enter the bodies of the organisms and to occur in the food vacuoles, but there was no evident increase either in the size of the organisms or in their rate of fission. Obviously, the dye is not responded to by protozoa as it is by epithelium; perhaps this specific response is somewhat similar to conditions in experiments with inorganic catalyzers. In these experiments, both a suspenoid [colloidal Pt] and an emulsoid [gutta percha] were used. It is to be remembered that the study of inorganic catalyzers has been carried on principally with the latter group, but this does not mean that the former one is not promising, or for *a priori* reasons should not be expected to give results, except in so far as it does not follow the criterion of Emil Fischer<sup>9</sup> of a stereochemical relation, wherein enzymes of whatever nature are defined as optically active catalyzers; platinum black is not optically active, which may account for its inability to influence organisms. The same may be said of the gutta-percha solution.

P. S.—Since the above account of my experiments was written, there has appeared a very

### SOCIETIES AND ACADEMIES

#### THE AMERICAN PHILOSOPHICAL SOCIETY

At a meeting of the society on February 7 Dr. Paul Heyl presented a paper on "Platinum in North Carolina." A belt of platinum-bearing rock runs from Danville, Va., to Cedar Falls, N. C., a distance of some seventy miles. Assays of as much as 4 or even 8 ounces per ton are occasionally found, but the average content is too small to be commercially important. The platinum in the rock is very rich in iridium. The deposit has been known for about seventeen years. An examination of the watershed of the region for 200 miles from the center for placers yielded negative results.

On March 7 the following paper was presented: "A Historical Account of the Early Microscopical Studies in the Structure of Animals and Plants with Reference to the Development of the Cell Theory," illustrated by lantern slides, by R. M. Pearce, professor of research medicine, University of Pennsylvania.

A sketch of the work of Hooke, Malpighi, Grew, Swammerdam and Leeuwenhoek in the last third of the seventeenth century, with remarks on the early microscopes, followed by the story of the development of our knowledge of plant and animal structure, as Lieberkuhn's (1739-48) studies of the finer structure of animal tissue, Trembly's (1744-47) observations on the division of protozoa, Brown's (1833) description of the nucleus and Treviranus's (1806) and Mohl's (1828) studies of the vegetable cell. A discussion of the improvements in the microscope up to 1830 and of the fundamental observations of Schleiden (1838) and Schwann (1839) which, followed by those of Virchow (1858), definitely established the cell theory. A short discussion of later work on the nature of cell protoplasm (Dujardin, Schultze) and the study of the nucleus and the process of division of cells, concluding with Flemming's observations in 1882. Illustrated by lantern slides showing

many of the original drawings which accompanied the reports of the various fundamental observations.

#### THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 33d annual meeting was held in the hall of the Cosmos Club, December 14, 1912, with Vice-president W. P. Hay in the chair. Reports of officers for the year 1912 were received and the annual election of officers took place. The election resulted as follows:

*President*—E. W. Nelson.

*Vice-presidents*—J. N. Rose, Paul Bartsch, W. P. Hay, A. D. Hopkins.

*Recording Secretary*—D. E. Lantz.

*Corresponding Secretary*—N. Hollister.

*Members of Council*—Hugh M. Smith, Vernon Bailey, Wm. Palmer, A. B. Baker and A. K. Fisher.

THE 505th regular meeting was held January 11, 1913, with President E. W. Nelson in the chair and 54 persons present. The chairman appointed standing committees on publications and communications for the year.

C. V. Piper exhibited a vase made of wood and covered with a thin veneer of "silk-wood." This veneer is cut from one of the large *Polyporus* fungi and takes a beautiful polish.

A. S. Hitchcock and E. W. Nelson each reported his recent return from a successful collecting trip, the former having collected grasses in Jamaica, Trinidad and Tobago, while the latter had secured birds and mammals in Arizona.

The regular program consisted of three communications:

*The Rediscovery of *Oenothera grandiflora**: S. M. TRACY.

The speaker gave an account of two trips made by him to the locality of Bartram's original discovery of this species (1776). The locality is near Dixie Landing, Alabama, and the flower described by Bartram was found abundant over a limited area. A second visit was made last year in company with Dr. Hugo de Vries.

*The Problem of the Identity of *Oenothera Lamarckiana**: H. H. BARTLETT.

The speaker gave a history of various cultivated strains of plants of this species and its hybrids. He predicted that its original habitat and identity—as yet unknown—would eventually be discovered, probably in America south of the United States and on the Pacific Slope.

*Sawflies and their Relations to Forestry*: S. A. ROHWER.

These very destructive insects were classed as defoliators and wood borers, and many instances of serious damage by them to growing timber were given. The paper was illustrated by numerous lantern slides showing various species of sawflies—adults, pupæ and larvæ—and also illustrations of damaged timber.

THE 506th regular meeting was held January 25, 1913, with the president in the chair and 47 persons present.

The following resolution relating to zoological nomenclature was presented to the society with the endorsement of the council and adopted unanimously:

Whereas certain zoologists have gone on record as favoring

1. A permanent and increasing list of exceptions to the law of priority,

2. A return to the principle of elimination regardless of the generic types that have been designated under the rules, and

3. A rejection of the present unanimous vote rule that has obtained for so many years in the International Congress on Zoological Nomenclature.

Therefore, be it resolved by the Biological Society of Washington that we favor

1. The consistent application of the law of priority in all cases,

2. The acceptance of the first designation of a genotype, regardless of the method followed in designating it, and

3. The present unanimous vote rule as making for conservation and stability in nomenclature.

Under the heading Brief Notes, etc., Paul Bartsch exhibited a small photographic camera, with a number of small pictures made with it and enlargements of the same. He spoke briefly of its convenience and adaptability to field uses.

Barton W. Evermann reported that a wireless message had just been received from Agent Lembeck at the Pribilof Islands in which it was stated that the reindeer herds on St. Paul and St. George had increased during the past year from 37 to 65 animals and that all are in excellent condition.

The regular program consisted of two communications:

*Notes on the Biology of the Common Termites of the Eastern United States*: THOMAS E. SNYDER.

This paper was illustrated by many lantern slides and was discussed by E. A. SCHWARZ.

*The Biting Powers of Ants*: W. L. MCATEE.

The speaker's personal observations as well as instances gathered from many sources were cited to show the powers of these small animals. Messrs. E. A. Schwarz, A. C. Weed, A. D. Hopkins and the author of the paper took part in the discussion which followed.

THE 507th regular meeting was held February 8, with President Nelson in the chair and 57 persons present.

Professor Burt G. Wilder gave an illustrated lecture on "The Brain as a Guide to the Affinities of Vertebrates," basing his remarks primarily on the brain of the shark *Pentanchus* recently described by Smith and Radcliffe as the type of a new family. The speaker showed by means of diagrams the evolution of the selachian brain from the most primitive form found in *Chlamydoselachus* through the other Notidani to the typical sharks; and announced his conclusion, from the evidence afforded by the brain, that *Pentanchus* is not a notidanid. He did not venture, however, to say just what the systematic position of this shark may be until the vertebræ and intestine have been studied, although it is certainly not related to the Scylliorhinidæ, to which Regan<sup>1</sup> assigns it on the theory that the single dorsal fin is an abnormality.

In the discussion which followed, H. M. Smith said that in assigning *Pentanchus* to the order of ancient sharks, partly on account of the single dorsal fin, he and Mr. Radcliffe had been aware of characters in which this shark differs from typical Diplospondyli, but that no other course seemed expedient at the time the preliminary description was published. The vertebræ, while not diplospondylous, but modified cyclospondylous, are of a very primitive type, being only half the size of those in a scylliorhinid shark of the same length, with an extremely small centrum and a very large neural canal.

Theodore Gill discussed the subject at length, and agreed with Professor Wilder in attaching great taxonomic importance to the brain in sharks and rays. He had concurred in the assignment of *Pentanchus* to the Notidani, and now regarded it as the type of a peculiar family whose affinities remain to be determined.

D. E. LANTZ,  
Recording Secretary

## THE GRAMERCY ASBESTOS DRYING OVEN

This oven fills a long-felt want for a clean and substantially-constructed substitute for the ordinary copper ovens, the appearance of which, after a short time in the laboratory, make them very undesirable.

Constructed entirely of heavy asbestos wood, with exception of the base and rack for shelves. A removable sheet metal plate, which receives the heat of the burner, forms the bottom of the oven; the permanent base frame and legs are of cast iron (aluminum finish), making the oven most rigid; while the racks for the shelves, and framework of the door, are of cast aluminum, which is practically unaffected by laboratory fumes.

The chamber of the **Gramercy Asbestos Oven** is 12"x10" and is provided with perforated asbestos shelves which can be placed at any height desired. The door is fitted with an air regulator. A ring gas burner is supplied with the oven, rigidly fitted, but most easily removed when desired.

*Price net, \$16.50.*

# Graphical Methods

By CARL RUNGE, Ph.D.

*Professor of Applied Mathematics in the University of Göttingen; Kaiser Wilhelm Professor of German History and Institutions for the year 1909-1910*

8vo, cloth, pp. vii + 148.

Illustrated with diagrams.

Price, \$1.50 net; by mail, \$1.60.

Professor Runge has here set forth the graphical methods in their most generalized form, in order to facilitate their application to any problem, in no matter what field, with which they are mathematically connected. The book should be of great value to the astronomer, the physicist, the engineer, or whoever applies mathematical methods, in enabling him to find shorter ways of solving his problems.

## AVOGADRO'S LAW AND THE ABSORPTION OF WATER BY ANIMAL TISSUES IN CRYSTALLOID AND COLLOID SOLUTIONS<sup>1</sup>

### I. STATEMENT OF THE PROBLEM

FIFTEEN years ago, on an occasion similar to this, the writer stated that if the constitution of matter is the main problem of the physicist the constitution of living matter is the main problem of the biologist. To-day I will discuss the applicability of Avogadro's law, one of the most fundamental laws underlying the constitution of matter, to a group of life phenomena, namely the regulation of the amount of water in animal cells and tissues. According to Avogadro's law equal volumes of gases at the same temperature and pressure contain an equal number of molecules; or, in other words: In the gaseous state equal numbers of any kind of molecules enclosed in equal volumes have the same pressure at the same temperature. This law was extended to solutions by van't Hoff in the following form: All dissolved substances produce upon a membrane which prevents their diffusion but allows water to diffuse an osmotic pressure equal to that which would be produced by gaseous matter containing the same number of molecules in the same volume. Combining Avogadro's and van't Hoff's law we may state that the same number of molecules of any kind of matter produce at the same temperature and volume the same pressure upon the walls which prevent their diffusion.

<sup>1</sup> Read by title in the Botanical Section of the Cleveland meeting of the Society of American Naturalists, December, 1912.

It is well known that Pfeffer constructed cells of clay whose pores were filled with a precipitate of ferrocyanide of copper and that the walls of these cells allowed water, but not salts or sugars, to diffuse through. When such a cell with semi-permeable walls is filled with a salt or sugar solution and put into a 'larger vessel' containing distilled water, the latter will diffuse into the cell and raise the level of the liquid until the hydrostatic pressure is equal to the osmotic pressure of the solute. Such a cell could therefore be used for the determination of the molecular weight of any dissolved substance which can not pass through its walls.

Now, if it be true that living cells are surrounded by semi-permeable walls and that the osmotic pressure regulates the exchange of water between the cells (or tissues) and the liquids of the animal body, it should also be possible to use living cells as osmometers for the determination of the molecular weight of sugars or salts.

The reader is aware that this possibility had already been demonstrated for plant cells (*Tradescantia*) by de Vries before van't Hoff had discovered the applicability of Avogadro's law to liquids and that de Vries's observations induced van't Hoff to interest himself in this problem. At the time of de Vries's work there was a difference of opinion concerning the molecular structure of the sugar raffinose and three different formulæ were offered, one giving the sugar the molecular weight 396, the second 594 and the third 1,188.

By determining the concentrations of cane sugar and raffinose which cause plasmolysis, *i. e.*, the shrinking of the protoplasm of the *Tradescantia* cells, de Vries found that a 3.42 per cent. cane sugar solution and a 5.96 per cent. raffinose solution had the same physiological effect. On the basis of the assumption that solutions with

an equal attraction for water have the same number of molecules in equal volumes, and since the molecular weight of cane sugar is 342, the molecular weight of raffinose should be  $(5.96/3.42) \cdot 342 = 596$ . In this way it was established by de Vries that the molecular weight of raffinose was 594 and the formula  $C_{18}H_{30}O_{16} + 5H_2O$  the correct one.<sup>2</sup> This formula for raffinose is to-day accepted by the chemists.

## II. EXAMPLES FOR THE APPLICABILITY OF AVOGADRO'S LAW TO THE OSMOTIC BEHAVIOR OF ANIMAL TISSUES

The oldest and, perhaps, best demonstration of the fact that the exchange of water between animal cells and the surrounding liquid is determined by Avogadro's law is furnished by Hedin's experiments on red blood corpuscles. His method consisted in the determination of the changes of volume of red blood cells in various solutions. The volume was determined with the centrifuge.

Hedin<sup>3</sup> first established the fact that the blood cells do not change their volume if put into solutions of the same molecular concentration as the blood, no matter what the nature of the solution, provided that the substance does not enter the cell.

VOLUME OF BLOOD CORPUSCLES IN				
.15m	KNO <sub>3</sub>	NaCl	NaCH <sub>3</sub> COO	CaCl <sub>2</sub>
	34.4	34.4	34.3	34.3

All the solutions had the same osmotic pressure as a .15m KNO<sub>3</sub> solution. The agreement of the results is such that the use of red blood corpuscles as osmometers for the determination of the molecular

<sup>2</sup> After Hoeber, *Physical. Chemie d. Zelle u. Gewebe*, 1911, p. 86; De Vries, *Jahrb. f. wissenschaft. Botanik*, Vol. 14, p. 427, 1884.

<sup>3</sup> Hedin, *Skand. Arch. f. Physiologie*, Vol. 5, pp. 207 and 238, 1895. (The tables quoted here are taken from Hamburger, "Osmotischer Druck und Ionenlehre.")

weight of dissolved substances would be warranted.

The following gives the results of the change in the volume of red blood corpuscles in isosmotic concentrations of  $\text{KNO}_3$  and  $\text{NaCl}$ .

Concentration	Volume of Blood Corpuscles in		Difference, Per Cent.
	$\text{KNO}_3$	$\text{NaCl}$	
.08m	48.6	50.2	-1.6
.1	46.3	48.2	-1.9
.12	43.2	44.2	-1.0
.13	42.5	43.4	-0.9
.14	41.4	42.2	-0.8
.15	40.2	41.0	-0.8
.16	39.9	40.4	+0.5
.17	39.7	39.6	+0.1
.18	39.4	39.2	+0.2
.20	39.1	38.0	+1.1
.22	39.2	37.3	+1.9
.24	38.7	36.8	+1.9
.26	38.3	36.5	+1.8
.30	37.2	36.8	+0.4

The agreement is best for .17  $\text{KNO}_3$  which was equi-molecular with the blood used in this case.

But even for concentrations differing from the molecular concentration of the blood the agreement is still surprisingly satisfactory, considering the fact that solutions which differ widely in their concentration from that of the blood corpuscles are liable to modify the permeability of the cells, as we shall see later; and that this injurious effect is influenced strongly by the chemical nature of the substance.

We may, therefore, state that equi-molecular solutions of salts cause practically the same change in the volume of red blood corpuscles.

The experiments on red blood corpuscles have the disadvantage that we can not well discriminate between the living and dead cell. In this respect the experiments on muscle are much more satisfactory. It had been known through the experiments of Nasse that in an m/8 solution of  $\text{NaCl}$  (and other salts of  $\text{Na}$ ) the frog's muscle keeps

its weight. The writer showed sixteen years ago that (within certain limits of time) the same is true for solutions of  $\text{LiCl}$ ,  $\text{KCl}$ ,  $\text{MgCl}_2$ ,  $\text{CaCl}_2$ ,  $\text{SrCl}_2$  and  $\text{BaCl}_2$  equi-molecular with an m/8  $\text{NaCl}$  solution, while in solutions of lower concentration the muscle absorbs, in solutions of higher concentration it loses water. He concluded from this that the absorption of water by the muscle is determined by van't Hoff's law.<sup>4</sup> The number of molecules in solution, and not their chemical character, determines the exchange of water between muscle and surrounding solution.

I was interested to find out with what degree of accuracy Avogadro's law determines the exchange of water in the muscle. For this purpose a series of experiments were made with  $\text{NaCl}$  and various sugars in concentrations slightly below or above the point of isotony.

CHANGE IN WEIGHT OF A FROG'S MUSCLE WITHIN  
ONE HOUR IN PER CENT. OF ITS ORIGINAL  
WEIGHT IN

.1	.125	.150	.175m $\text{NaCl}$
+ 3.9%	0%	- 1.9%	- 1.9%

In a .1m solution of  $\text{NaCl}$  the muscle takes up water, in a .125m solution it keeps its weight, in a .15 solution it loses water. That the loss in a .175m solution was in this case not greater than in a .15 solution was accidental and probably due to the fact that different muscles vary somewhat in their osmotic pressure, owing to their previous history—*e. g.*, whether they had been more or less active. The influence of these inequalities can be eliminated by making a large number of experiments.

But, although the muscle is not quite as accurate an osmometer as the red blood corpuscles, the fact that its exchange of water is determined primarily by Avo-

<sup>4</sup>Loeb, *Pflüger's Archiv*, Vol. 69, pp. 14-20, 1897.

gadro's law is illustrated by the following experiment.

In an m/8 solution of NaCl 85 per cent. of the molecules are dissociated into ions. If we want to prepare solutions of non-conductors (*e. g.*, sugars) of the same osmotic pressure as an m/8 NaCl we must choose a concentration of .231m. At a concentration of a sugar solution of .200m a muscle must absorb water, while at a concentration of .250 and above it must lose water. We have made this experiment for three sugars, a mono-saccharide, grape sugar; a disaccharide, cane sugar; and a trisaccharide, raffinose. The following table gives the change in weight of the muscle in these solutions in one hour.

	.2m	.25m	.3m	.35m
Grape sugar.....	+2.9%	-1.6%	-4.1%	-7.7%
Cane sugar.....	+3.8%	-1.2%	-1.3%	-6.1%
Raffinose.....	+1.7%	-3.3%	-5.3%	-8.9%

The turning point between loss and gain of weight lies for all those sugars between the same limit of molecular concentration, namely, between .2 and .25m; and the most important fact is that the value for the three different sugars lies between the limits calculated on the assumption that the exchange of water between muscle and surrounding solution is determined by Avogadro-van't Hoff's law. As long as we are dealing in biology with only qualitative results there may always be some doubt in regard to the applicability of such a law to a life phenomenon, but if the results come out quantitatively identical with those calculated we may be pretty sure that the law holds good for these cases.

Miss Cooke<sup>5</sup> investigated in the writer's laboratory the gain of weight in the muscle in hypotonic and hypertonic NaCl solutions. Near the isotonic point the amount

of water increases at first slowly in almost a straight line with the dilution; but as the solutions become more dilute the amount of water taken up increases at a rate far greater than the rate of dilution of the solution. Miss Cooke points out that this may be due to some secondary change in the muscle caused by the dilute solution or the entrance of water into the muscle. In hypertonic solutions irregularities were noticeable, due probably to the varying condition of rest or activity in the individual muscle before the experiment.

The following gives a series of determinations in equi-molecular solutions of NaCl and cane sugar, by R. Webster.<sup>6</sup>

CHANGE IN WEIGHT OF FROG'S GASTROCNEMIUS  
AFTER ONE HOUR IN EQUI-MOLECULAR SOLUTIONS OF NaCl AND CANE SUGAR.

NaCl		Cane Sugar	
	Per Cent.		Per Cent.
m	-17	1.67m	-40
m/2	-13	.87m	-27
m/4	-7	.45m	-12
m/8	0	.23m	-1
m/16	+13	.12m	+11
m/32	+25	.05m	+26

While the gain in weight of the muscle in the equivalent hypotonic solution is practically the same in NaCl and cane sugar, in the hypertonic solutions of cane sugar the muscle loses more than in the equi-molecular solutions of NaCl. This is probably due to the fact that solutions of cane sugar have an abnormally high osmotic pressure and that this anomaly seems to be more pronounced the higher the concentration.

The number of animal organs in which the applicability of Avogadro's law can be tested is limited, since for this purpose it is necessary that the tissues have no pores or capillary spaces in which the surround-

<sup>5</sup> *Journal of Physiology*, Vol. 22, p. 137, 1898.

<sup>6</sup> R. Webster, University of Chicago Decennial Publications, Vol. X., p. 105, 1902.

ing solution can adhere. Tissues with a spongy structure can not be used for exact measurements. Siebeck<sup>7</sup> has recently been able to carry out a series of experiments on the kidneys of the frog. The measurements were not as satisfactory as in the case of the red blood corpuscles and the muscle, but sufficiently accurate to leave no doubt of the main result, which is as follows: In solutions of NaCl, NaBr, LiCl, and LiBr, KCl, CaCl<sub>2</sub>, MgCl<sub>2</sub> and cane sugar equi-molecular with a .7 per cent. Ringer solution the kidneys neither take up nor lose water. Siebeck points out that these solutions have no other quality in common except the same number of molecules, and that hence the osmotic pressure determines the exchange of water between the kidneys and the surrounding solution. Mathews's experiments indicate that the same is true for the living nerve.<sup>8</sup>

According to Meigs' smooth muscle preparations do not behave as if they were surrounded by semi-permeable membranes; but the smooth muscle of the stomach which he used in his experiments can not be obtained in as natural a condition as that in which striped muscle or blood corpuscles or the kidneys are available. It would be of interest to repeat these experiments on smooth muscle, which can be obtained with as little alteration of its natural surface, as, *e. g.*, striped muscle or kidneys or red blood corpuscles.

### III. ABSORPTION OF WATER BY COLLOIDAL SOLUTIONS

The natural media surrounding animal tissues are solutions which contain dis-

<sup>7</sup> Siebeck, *Pflüger's Archiv*, Vol. 148, p. 443, 1912.

<sup>8</sup> A. P. Mathews, *Am. Jour. Physiol.*, Vol. II., p. 455, 1904.

<sup>9</sup> *Journal of Exper. Zoology*, Vol. 13, p. 498, 1912.

solved proteins in addition to certain salts. Some authors seem to take it for granted that the force by which such protein solutions or colloidal solutions in general absorb water is not determined by Avogadro's law, and some go so far as to state that the regulation of the distribution of water between cells and blood is solely determined by the proteins and not by the salts. Such ideas are contradicted by theory as well as by experiment. We can show by the use of living cells as osmometers that colloidal solutions behave exactly as Avogadro's and van't Hoff's laws demand.

Avogadro-van't Hoff's law demands that a gramolecular solution of any dissolved substance contain the same number of molecules—leaving aside temporarily the facts of dissociation—and this number  $N$  is Avogadro's constant. As is well known, the value of  $N$  has been determined for molecules with an astonishing degree of agreement by the most diverse methods. Thus Rutherford found  $N=62.10^{22}$  by counting the  $\alpha$  particles given off by a given quantity of radium per second; and Dewar as well as Boltwood obtained identical values,  $71.10^{22}$ , by a similar method.

A method of calculating  $N$  from the constants of heat radiation gave, according to a theory of Lorentz,  $N=62.10^{22}$ . Lord Rayleigh determined the number  $N$  of molecules in a gram molecule from the diffusion of light from the sky and found  $N$  about  $70.10^{22}$ .<sup>10</sup>

It would seem *a priori* perhaps doubtful whether or not the suspended particles of a colloidal solution behave like molecules. Perrin undertook to solve this problem. He points out that van't Hoff's law (for properly dilute solutions) is applicable, no

<sup>10</sup> These data are taken from Arrhenius, "Theories of Solutions," New Haven, 1912, pp. 25 and 26.

matter whether molecules are small or large, light or heavy.

Can we not suppose under these circumstances that there is no limit of size for the particles which obey this law? Should it not be possible that even visible particles obey this law exactly, so that a granule, agitated by brownian movement, counts neither more nor less than an ordinary molecule in regard to the action of its shocks on a wall which blocks its progress? Or, in other words, may we not assume that the laws of perfect gases can be applied to emulsions made of visible granules.<sup>14</sup>

It is well known that Perrin determined the value of  $N$  from the measurement of the relative distribution of the suspended particles of an emulsion of mastix in a vertical column and found  $N = 62.2 \cdot 10^{22}$ . Almost identical values were obtained by him by three other methods. This proves that as far as osmotic pressure is concerned the suspended particles of an emulsion behave exactly like the molecules of a gas.

Direct osmometric measurements of the osmotic pressure of proteins gave very low figures, as was to be expected from their high molecular weight. R. S. Lillie found 30 to 40 mm. Hg for a 2 per cent. solution of albumen,<sup>15</sup> Starling for the proteins of blood serum 40 mm. Hg.

The question may now be asked whether or not the proteins in solution have other qualities by which they attract water than their osmotic pressure? This question can easily be answered by using living cells as osmometers. We have seen that an  $m/8$  NaCl or a .231m sugar solution are isotonic with a frog's muscle (gastrocnemius). The latter solutions have an osmotic pressure of 3933 mm. Hg. We have also seen that as an osmometer a frog's gastrocnemius may be considered accurate at the point of isotony within .03m sugar. Hence the osmotic pressure

of the proteins of the blood is below the limit of sensitiveness of the muscle as an osmometer; or, in other words: if the attraction of water by blood is determined solely by the osmotic pressure of the blood that part of its total osmotic pressure which is furnished by the proteins must be negligible. This is indeed the case.

I asked my assistant, Dr. Beutner, to compare the change in weight of a frog's muscle in various solutions with and without proteins.<sup>13</sup>

CHANGE IN WEIGHT OF TWO GASTROCNEMII OF  
THE SAME FROG

	Muscle <i>a</i> in $m/8$ Ringer, Per Cent.	Muscle <i>b</i> in $m/8$ Ringer + 2 Per Cent. Gelatine. Per Cent.
After 1 hour . . . .	— 1.6	— 2.5
After 3 hours . . . .	— 3.5	— 4.3
After 8 hours . . . .	— 3.2	— 4.7
After 22 hours . . . .	— 4.4	— 3.8
After 29 hours . . . .	— 4.2	— 3.8

The differences in the two rows of figures are slight in comparison with the experimental errors and show that the addition of gelatine does not influence noticeably the absorption of water.

In a second experiment it was ascertained that in blood serum which was freed from the greater part of its salts by dialyzing it for 40 hours through parchment paper the muscle gains exactly as much in weight as it does in a NaCl solution of the same osmotic pressure. The serum had after dialyzation a freezing point depression of .03°, corresponding to a concentration of NaCl of about  $m/120$ .

CHANGE IN WEIGHT OF TWO GASTROCNEMII OF  
THE SAME FROG

	Muscle <i>a</i> in Dialyzed Serum, Per Cent.	Muscle <i>b</i> in $m/120$ Ringer, Per Cent.
After $\frac{1}{2}$ hour . . . .	+ 22.3	+ 24.7
After 1 hour . . . .	+ 34.0	+ 38.0
After 2½ hours . . . .	+ 51.0	+ 53.6

<sup>14</sup> Perrin, "Les Atomes," Paris, 1912, p. 128 ff.

<sup>15</sup> Lillie, *Am. Jour. of Physiol.*, Vol. 20, p. 197.

<sup>13</sup> R. Beutner, *Biochemische Zeitschr.*, Vol. 48, p. 217, 1913.

These two series of results may be considered as identical within the limits of error. They prove that proteins in solution attract water from the muscle solely according to their osmotic pressure and not according to any other real or assumed quality. They prove also that the salts and not the proteins of the blood determine the exchange of water with the tissues.

R. Lillie has shown that the addition of acid increases the osmotic pressure of a protein solution, but the increase is too small, even in dialyzed serum, to influence the velocity of water absorption, as the following figures show.

CHANGE IN WEIGHT OF TWO MUSCLES

	Muscle a in 50 c.c. Dialyzed Serum +1 c.c. N/10 HCl, Per Cent.	Muscle b in Dialyzed Serum without Acid, Per Cent.
After 1 hour ...	+ 33.0	+ 35.0
After 2 hours ..	+ 43.0	+ 46.0
After 4 hours ..	+ 52.0	+ 49.0
After 6 hours ..	+ 45.0	+ 43.0

I think all these experiments prove conclusively, (1) that colloidal solutions influence the absorption of water in the tissues solely by their osmotic pressure; and (2) that this osmotic pressure is so small in comparison with that of the salts in the liquids of the body that their influence is in general practically negligible.<sup>14</sup>

#### IV. PERMEABLE AND NON-PERMEABLE SOLUTIONS

The existence of semi-permeable walls which allow the water but not the solute

<sup>14</sup>The erroneous idea that the attraction of water by blood serum is determined by proteins may have originated through the arbitrary assumption that the phenomenon of imbibition found in solid colloids is retained by the colloids in solution. This reasoning is, however, not warranted, since it is possible that in solid colloids conditions for the absorption of water may exist which cease to exist when the colloid is dissolved.

to diffuse is the prerequisite for the manifestation of osmotic pressure. It is well known that Overton showed that dissolved substances which diffuse easily into the cell do not produce any osmotic effect. The permeability of cell walls for alkaloids can be directly demonstrated by their reaction with the tannic acid of the cells, and Overton showed that when added to an isotonic salt solution the alkaloids will not alter the water equilibrium. The substances which thus diffuse readily into the cells are alcohols, aldehydes and many other compounds which often show a relatively high degree of solubility in lipoids. The difference in the behavior of substances which are soluble in the cell wall (like alcohol) and non-soluble (like sugar) is illustrated by the following experiments by Overton.<sup>15</sup>

In 0.2 per cent. NaCl + 2.66 per cent. mannit (together equi-molecular with .7 per cent. NaCl) the gastrocnemius of a frog kept its weight for nine hours unaltered. In 0.2 per cent. NaCl + 2 per cent. methyl alcohol (approximately equi-molecular with a 1.6 per cent. NaCl solution), the muscle absorbed water as powerfully as in a pure 0.2 solution of NaCl. Only those substances which can not diffuse into the cell can assist in the exchange of water between tissues and the liquids of the body; exactly as Avogadro's law demands.

It is generally assumed that there is only one type of semi-permeable membranes, namely, those permeable for water, but not for neutral salts or sugars. This type is the most common. But there are at least two other types of semi-permeability. Some membranes are permeable for water as well as salts and sugars, but not for colloids. The fertilization membrane of the sea urchin egg (*Strongylocentrotus*

<sup>15</sup>Overton, *Pflüger's Archiv*, Vol. 92, p. 115, 1902.

*purpuratus*) belongs to this type.<sup>16</sup> On the other hand, there are membranes which are neither permeable for salts nor for water. This type of membranes is represented by the eggs of *Fundulus*, and apparently *Fundulus* itself, and probably by a large number of other aquatic vertebrates.

All these membranes are, however, permeable for gases ( $O_2$  and  $CO_2$ ) dissolved in water.

#### V. THE APPARENT CONTRADICTION BETWEEN THE PHYSIOLOGICAL EFFICIENCY OF SALTS AND THE SEMI-PERMEABILITY OF CELL WALLS

We will now discuss a difficulty which the idea of impermeability of the cells for salts has to meet. In a pure NaCl solution the frog's muscle begins to twitch, while the addition of a little Ca inhibits this effect. It is difficult to assume that salts act without diffusing into the cell, and yet the phenomena of isotony are incomprehensible without the assumption of practical impermeability of the cell for salts and sugars. This difficulty is apparently relieved by the investigations of Loeb and Beutner<sup>17</sup> on the potential differences at the limit between living organs and the surrounding solution of electrolytes. If we form a cell of the type: solution of electrolyte (concentrated); living organ; solution of electrolyte (dilute), the dilute solution is positive towards the concentrated; and the more so the greater the dilution. This seems to be a fact for most living tissues. From this it follows that living tissues are reversible for kations. We were, moreover, able to show that the electromotive forces of such cells obey

Nernst's law, according to which the E.M.F. varies with the logarithm of the concentration. But the most surprising fact we found was that the living cells are reversible in regard to practically any kation, while the potential differences heretofore observed by physicists at the limit of two phases were only reversible for one kation. These results are only intelligible on one of two assumptions: either the surface of all living organs contains already traces of all metals, which is not very probable; or traces of the electrolytes react with the surface of the living organ. If the latter is true we can understand that electrolytes can influence the life phenomena and yet produce the theoretically calculated osmotic pressure upon the walls of living organs.

The writer suggested thirteen years ago that chemical reactions occur between the electrolytes and certain parts of the "protoplasm"—proteins or fatty compounds—which result in the formation of ion or metal-proteins or soap-like compounds, and that these reactions explain the influence of the electrolytes upon muscular twitchings, heart beat, etc. It is well known that the action of salts like NaCl or  $CaCl_2$  or KCl upon the heart beat or muscular twitchings is—within certain limits of concentration and time—perfectly reversible, and this reversibility is characteristic of this action. Such a complete reversibility of chemical reactions is intelligible if only traces of the salts enter into reaction with the substances contained in the living organ.

Beutner reached the conclusion on the basis of thermodynamical calculations that the potential differences observed by us at the junction of living organs and surrounding solution demand the assumption of a chemical reaction between traces of

<sup>16</sup> Loeb, *Roux's Archiv*, Vol. 26, p. 82, 1908.

<sup>17</sup> Loeb and Beutner, *Biochemische Zeitschr.*, Vol. 41, p. 1, 1912; Vol. 44, p. 303, 1912.

the electrolyte and the surface of the living organ.<sup>18</sup>

VI. THE ALTERATION OF THE SEMI-PERMEABILITY OF CELL WALLS BY ELECTROLYTES

Those who have worked with Pfeffer's semi-permeable cells report that it is very difficult to maintain cells in the state of ideal semi-permeability. It seems that the semi-permeability of living organs suffers also if they are exposed to solutions abnormal in concentration or constitution or both. The normal medium for the cells of our body is a liquid which contains NaCl, KCl and  $\text{CaCl}_2$  in a proportion which is almost identical with the one in which those salts appear in the ocean. In such solutions, if their concentration is right, the cell walls may keep their specific semi-permeability as long as they live. If, however, the cells or organs are put into solutions of other salts, or of solutions with only one of the three salts just mentioned, the semi-permeability is lost sooner or later and death follows. The possible explanation is that the interactions between salts and surface of the living organ lead in this case to a modification of the physical qualities of the surface of the living organ.

In 1899 the writer found that the newly fertilized eggs of a marine fish, *Fundulus*, will develop normally in distilled water and the fish will hatch. If, however, the eggs are put into an  $\text{m}/2$ , or still better  $\frac{1}{2}\text{m}$ , NaCl solution immediately after fertilization they will die without forming an embryo. If a small but definite amount of a salt with a bivalent metal is added to the NaCl solution the eggs will form embryos. The explanation of these facts is as follows:

If the newly fertilized eggs are put into a  $\frac{1}{2}\text{m}$  NaCl solution the NaCl makes the egg membranes, which are naturally impreg-

nable to salts, gradually permeable. NaCl enters the egg and the germ is killed. If a little Ca is added to the NaCl this modification of the membrane is inhibited, no NaCl enters the egg and the germ can live and develop. In distilled water the membrane remains also impermeable to salt (and to water) and the embryo likewise develops.<sup>19</sup>

The writer has recently published a series of experiments which furnish a proof for this assumption.<sup>20</sup> Only the general character of this proof can be indicated here. The eggs of *Fundulus* have a specific gravity of a little over 1.0580 (corresponding to  $\frac{1}{2}\text{m}$  NaCl solution). If such eggs several days after fertilization are put into a 3m solution of NaCl + KCl +  $\text{CaCl}_2$  in the proportion in which these three salts occur in the sea-water, the eggs will float at the surface of the solution for four days or longer. Then they will shrink and fall to the bottom of the test tube. The membrane is impermeable to water and salts and remains so for a series of days even in a 3m solution of NaCl + KCl +  $\text{CaCl}_2$ . Finally it becomes permeable for water and to a lesser degree for salts and the eggs shrink and fall to the bottom. If, however, the eggs are put into a 3m solution of NaCl they will also float at first; but the increase in permeability and the shrinking begins in three hours. If we put the eggs into a solution of  $\text{CaCl}_2$  from  $\frac{1}{2}\text{m}$  to  $2\frac{1}{2}\text{m}$  they float at first, but the shrinking begins in 20 minutes and the eggs sink to the bottom. If we put the eggs into a mixture of 48 c.c. 3m NaCl + 2 c.c.  $\frac{1}{2}\text{m}$   $\text{CaCl}_2$  they will

<sup>19</sup> Loeb, SCIENCE, Vol. 34, p. 653, 1911. Reprinted in "Mechanistic Conception of Life," Chicago, 1912; *Pflüger's Archiv*, Vol. 107, p. 252, 1905.

<sup>20</sup> Loeb, *Biochemische Zeitschr.*, Vol. 47, p. 127, 1912.

<sup>18</sup> Beutner, *Biochem. Zeitschr.*, Vol. 47, p. 73, 1912.

float for three days, before they begin to shrink and fall to the bottom. This and similar experiments show that the specific semi-permeability of an animal membrane is influenced by the nature of the solutions to which it is exposed. In physiologically balanced solutions, *e. g.*,  $\text{NaCl} + \text{KCl} + \text{CaCl}_2$  in the proportion in which these salts exist in the sea-water, this specific semi-permeability is preserved longest, if not permanently. In solutions of one salt only the permeability is as a rule increased as soon as the concentration of the salt in the solution exceeds a certain limit. This limit varies for different salts and varies also for the same salt in different animals. This is the reason why a pure  $\text{NaCl}$  solution becomes injurious more rapidly to one form of organism than to another. The reader will notice that in this field of phenomena the chemical nature of the solution is of primary importance.

This dependence of the preservation of semi-permeability upon the chemical nature of the surrounding solution suggests the possibility of a chemical interaction between cell walls and surrounding solution in which the chemical and physical properties of the semi-permeable wall are modified.

#### VII. THE DIFFERENCE IN THE MODE OF ABSORPTION OF WATER IN LIVING AND DEAD CELLS

We may conclude from the preceding data that the salts of the surrounding solution react chemically with the colloids of the surface of the cell and that the products thereby formed determine the degree of permeability or impermeability of the cell walls.

These changes vary with the chemical nature of the salt. In some solutions the permeability is preserved much longer than in others. Thus the muscle keeps its

normal function much longer in a  $\text{NaCl}$  or a  $\text{LiCl}$  solution than in a solution of  $\text{KCl}$  or  $\text{CaCl}_2$ . As long as the muscle is irritable or even some time after it ceases to be irritable it obeys Avogadro's law in the solutions of pure salts. After 18 hours, however, the muscle is killed in pure isotonic solutions of  $\text{KCl}$  as well as of  $\text{CaCl}_2$ , while it is still alive in solutions of  $\text{NaCl}$  and  $\text{LiCl}$ . At that time it continues to obey the law of Avogadro in  $\text{NaCl}$  and  $\text{LiCl}$ , but no longer in  $\text{KCl}$  and  $\text{CaCl}_2$ .

CHANGE IN WEIGHT OF A GASTROCNEMIUS OF A  
FROG AFTER 18 HOURS IN SOLUTIONS EQUI-  
MOLECULAR WITH  $m/8 \text{ NaCl}$  <sup>21</sup>

	Per Cent.		Per Cent.		Per Cent.		Per Cent.
$\text{LiCl} \dots$	-1	$\text{NaCl} \dots$	+6	$\text{KCl} \dots$	+45.7	$\text{CaCl}_2 \dots$	-20
$\text{LiBr} \dots$	-1	$\text{NaBr} \dots$	+7	$\text{KBr} \dots$	+41		
$\text{LiJ} \dots$	-3	$\text{NaJ} \dots$	+10	$\text{KJ} \dots$	+45		

While the muscle undergoes no, or only slight, changes in weight in the isotonic solutions of  $\text{Na}$  and  $\text{Li}$  salts it absorbs a considerable amount of water in  $\text{KCl}$ , loses water in  $\text{CaCl}_2$ .

Overton, who later repeated and confirmed these results, explained them on the assumption that the normal muscle is permeable for  $\text{KCl}$ , but not for the other salts. In a pure  $\text{KCl}$  solution the salt gradually enters the muscle, whereby the osmotic pressure of the muscle is increased and the latter swells; while in a  $\text{CaCl}_2$  solution the  $\text{KCl}$  naturally contained in the muscle leaves the muscle and the diminution of the number of molecules in the muscle makes the surrounding originally isotonic solution hypertonic for the muscle. One fails to see, on such an assumption, why the muscle does not also lose water in a  $\text{NaCl}$  solution. It has been demonstrated

<sup>21</sup> Loeb, *Pflüger's Archiv*, Vol. 75, p. 304, 1899;  
"Studies in General Physiology," Vol. II., p. 511,  
Chicago, 1906.

that the normal gastrocnemius of a frog contains little or no NaCl, but comparatively much KCl, while in the blood the reverse is the case. From this it has been plausibly argued that the NaCl of the blood can no more enter the muscle than can  $\text{CaCl}_2$ . One fails, however, to see how on this assumption the fact can be explained that in a pure NaCl or LiCl solution the muscle keeps its weight or gains slightly, while in  $\text{CaCl}_2$  it loses considerably in weight, since in a pure NaCl solution the K-salts should leave the muscle as well as in a  $\text{CaCl}_2$  solution.

In all hypertonic solutions the muscle loses water and the higher the concentration of the solution is the more water it loses. This is what should be expected according to Avogadro's law. But the writer noticed that if the muscles remain in the hypertonic solution they begin after a certain time to absorb water and the higher the concentration the sooner, so that finally the muscle begins to swell even in a gramolecular solution of NaCl!

This paradoxical behavior finds its explanation in the writer's observations on *Fundulus* eggs, which show that the impermeability of the membrane for salts and sugars is destroyed the more rapidly the higher the concentration of a solution. As soon as this impermeability is destroyed the cells no longer follow Avogadro's law, but show a behavior which is comparable to that of a piece of solid gelatine, *i. e.*, water is absorbed not by osmotic forces but by "imbibition." The degree of imbibition varies with the nature of the surrounding salt and on this assumption the writer explained the differences of behavior of dead muscle in KCl and  $\text{CaCl}_2$  solutions.<sup>22</sup>

<sup>22</sup> Loeb, *l. c.*

#### VIII. THE ANTAGONISM BETWEEN ACIDS AND SALTS

The influence of the chemical character of the surrounding solutions upon imbibition in the dead muscle is well illustrated by the following observations:

The writer showed sixteen years ago that the muscle absorbs water from an m/8 solution of NaCl if HCl (or any other acid) is added.<sup>23</sup> In this case the law of Avogadro-van't Hoff is apparently violated. It was pointed out by Overton that in this case the acid destroys the semi-permeability of the muscle and that the subsequent absorption of water was a mere phenomenon of imbibition. It had been shown previously that the swelling of a solid plate of gelatine in water is increased if acid is added.

In a subsequent paper it was shown by the writer that there exists a curious antagonism between salts and acids. While a muscle swells in an m/8 NaCl solution if the latter is rendered acid, it does not swell, or it may be even dehydrated in an acid solution when the concentration of the NaCl in the solution is sufficiently raised; notwithstanding the fact that in the highly concentrated neutral NaCl solution the muscle will finally absorb water.

The following table illustrates this:

Neutral NaCl		m/110 HCl in NaCl	
Concentration of NaCl, Per Cent.	Increase in Weight in 18 Hours, Per Cent.	Concentration of NaCl, Per Cent.	Increase in Weight, Per Cent.
4.9	+6	4.9	-36
1.22	-2	1.22	+22.2
0.7	+7	0.7	+40

While the muscle gains in weight in eighteen hours in a neutral 4.9 per cent.

<sup>23</sup> Loeb, *Pflüger's Archiv*, Vol. 69, p. 1, 1897; Vol. 71, p. 457, 1898. "Studies in General Physiology," Vol. II, pp. 450 and 501, Chicago, 1906.

NaCl solution, it loses considerably in an m/110 acid 4.9 per cent. NaCl solution.<sup>24</sup>

The writer also pointed out that the chemical character of the salt was of great influence in this phenomenon. While it required a high concentration of NaCl and of acid to cause a dehydration, the same was accomplished by a much weaker solution of  $K_2SO_4$ . In a neutral isotonic solution of  $K_2SO_4$  the muscle lost 4 per cent. in eighteen hours, but when 10 c.c. m/10 HCl were added to 100 c.c. isotonic  $K_2SO_4$  solution the muscle lost 22 per cent. of its weight! The concentration of  $K_2SO_4$  required to inhibit the swelling effect of the acid is therefore much smaller than that of NaCl.<sup>25</sup>

When a muscle is put into a .04m solution of  $Na_2SO_4$  which is rendered m/200 acid through the addition of  $H_2SO_4$ , the muscle first absorbs water and later is dehydrated, as the following experiment by Beutner<sup>26</sup> shows:

CHANGE IN WEIGHT OF MUSCLE IN .04m  
 $Na_2SO_4$  — N/200  $H_2SO_4$

1 hour .....	+ 9.9
3 hours .....	+ 12.3
6 hours .....	+ 1.8
24 hours .....	— 19.3
32 hours .....	— 25.2
96 hours .....	— 31.2

The interpretation of this result offers no difficulty. As Beutner pointed out, the muscle obeys the law of van't Hoff, as long as it is alive, or more correctly, as long as the semi-permeability of its membrane is preserved. Since a .04m solution of

$Na_2SO_4$  is hypotonic, the muscle must absorb water in such a solution. As soon as the semi-permeability of the muscle is lost and the acid diffuses into the muscle it behaves altogether differently, namely, like a piece of gelatine. Proctor has shown that solid gelatine swells in a salt solution as well as in an acid solution, while it is dehydrated in a combination of both; and the same is true for the dead muscle.

#### IX. INTERNAL CHANGES IN THE MUSCLE

Miss Cooke showed that the fatigued muscle of a frog is no longer isotonic with an m/8 solution of NaCl, but with a 3m/16 solution. The fatigue has, therefore increased the osmotic pressure of the muscle.<sup>27</sup> The writer suggested that in this case lactic acid was formed and that this lactic acid was the cause of the absorption of water by the muscle in an isotonic solution.<sup>28</sup> The lactic acid might act as a catalyzer in certain reactions, whereby the osmotic pressure would be raised in the muscle. Others assume that some colloid in the muscle is caused to swell by the acid. This could only refer to some solid colloid. But it is difficult to understand how this could force the muscle to absorb more water. Proctor<sup>29</sup> has shown that solid colloids absorb not only water, but also salts (even in the presence of acid); if this be the case the swelling of solid colloids inside the muscle can only increase the osmotic pressure of the liquids contained inside the muscle cells, if relatively more water is absorbed than salt. Since no quantitative data are available on this point, it is useless to argue the question.

<sup>24</sup> Loeb, *Pflüger's Archiv*, Vol. 75, p. 302, 1899. Reprinted in "Studies in General Physiology," Vol. II., p. 516, 1906.

<sup>25</sup> Loeb, *Pflüger's Archiv*, Vol. 75, p. 303, 1899; "Studies in General Physiology," Vol. II., p. 514.

<sup>26</sup> Beutner, *Biochem. Zeitschr*, Vol. 39, p. 280, 1912.

<sup>27</sup> In order to avoid misunderstandings it should be said that the fatigued muscle obeys Avogadro's law, only its point of isotony is increased.

<sup>28</sup> Loeb, *Pflüger's Archiv*, Vol. 71, p. 466, 1898.

<sup>29</sup> Proctor, "Kolloidchemische Beihefte," Vol. II., p. 262, 1911.

## CONCLUSION

I believe the facts mentioned in this address show that those animal cells or organs which lend themselves to exact measurements of osmotic changes obey the law of Avogadro-van't Hoff, as long as they are normal or alive: *i. e.*, they neither absorb nor lose water if put into solutions of any kinds of sugar or neutral salts which are equi-molecular with the blood; that they absorb water in solutions of lower osmotic pressure, lose water in solutions of higher osmotic pressure. If the law of Avogadro and van't Hoff is correct (which nobody doubts), this behavior of the tissues is the expression of the applicability of this law to the exchange of water between tissues and liquids of the body.

It does not often happen in biology that we are able to reduce life phenomena to a fundamental physico-chemical law to such an extent that we can not only predict the results qualitatively, but also quantitatively, as is the case in the application of Avogadro's law to the exchange of water between tissues and the liquids of the body.

If anybody wishes to supplant the law of Avogadro he must be able to offer a theory which allows a still closer approximation between calculated and observed results than is the case in the experiments on the absorption of water by animal cells or tissues. No such theory has thus far been offered.

THE SPREAD OF THE BROWN-TAIL AND  
GYPSY MOTH

FOR several years Massachusetts has been spending large sums of money in fighting the brown-tail and gipsy moths. These insects have spread westward in their devastating course and are now recorded from a point

not far distant from the eastern boundary of New York. In February a conference was called in Boston by the state forester of Massachusetts for the purpose of bringing together not only those actually engaged in the fight with the gipsy and brown-tail moths, but those who are sure to be concerned in the near future. The New York State College of Forestry at Syracuse University is investigating the work of these insects and Dr. M. W. Blackman, forest entomologist of the college, was its representative in the conference in Boston and is ready to take up the fight against these insects when they appear in this state.

Interesting facts were brought out at this conference as to the spread of the gipsy moth. It is very certain that New York and other states about Massachusetts will soon be reached by these destructive insects and that unless more effective means are taken they will destroy not only forest trees but shade and ornamental trees over large sections of the state. As shade tree pests these insects can be controlled by spraying and destroying egg clusters, but these methods are used only at considerable expense and must be continued indefinitely. It seems probable that as soon as the parasites and diseases introduced from abroad which work upon and destroy these insects have become fairly established that they will aid man greatly against future serious outbreaks.

The gipsy moth problem of the future in the state of New York is a forestry problem, as the insect can not be fought in the forest by spraying but must be controlled and eventually eliminated by proper methods of forest management. Certain trees, such as the oak, willow and birch, are apparently more favorable and often seem necessary for the development of the caterpillars of the moths. Methods of forest management can be used which will remove these trees from the forest and thus destroy the most favored food of the pests. With these methods of proper forest management must go strict quarantine against lumber, cordwood and nursery products shipped in from infested areas. Some effort

has been made to establish a "dead line" to prevent further spread of the insect. A zone of timber consisting largely of white pine and other evergreens is selected and all hardwoods or broad-leaf growth removed. As the insects are unable to complete their life history on the pines, they are checked and it may be possible to prevent their spreading northward into the Adirondacks, or into the Catskills, through the maintenance of such zones of coniferous growth. In the caterpillar stage the two moths do the greatest damage and the greatest spread of the insect occurs at this time. They are often blown long distances by the wind or carried by automobiles and other vehicles and much can be done in preventing this kind of distribution by keeping the roadside districts free of the caterpillars through spraying and the removal of their favored food plants.

The outbreak of the gipsy moth in this state in the summer of 1912 was not extensive and by prompt measures, such as the removal of infested trees, spraying, etc., the colony was destroyed. It is entirely possible, however, that there may be other well established colonies in outlying districts near the Catskills or Adirondacks of which there is no official knowledge. The state in the prosecution of its forestry work should make thorough investigations, especially along the eastern border in sections where there is the greater danger of the incoming of the caterpillar and thus prevent its doing the tremendous damage which it has done in Massachusetts.

#### THE NEW GEOLOGICAL SURVEY BUILDING

AFTER a campaign lasting 26 years the United States Geological Survey has received generous recognition at the hands of congress in the authorization of an expenditure of \$2,596,000 for the construction of a fireproof building "of modern office-building type of architecture." With this sum it is proposed to erect a building on ground already owned by the government which shall accommodate, besides the Geological Survey, the Reclamation Service, the Indian Office and the Bureau of Mines, all bureaus of the Interior Depart-

ment whose work is closely related to that of the Survey and among all of which there is more or less constant cooperation. The public buildings law, which carries the Survey item, authorizes an immediate appropriation of \$596,000, the balance to be appropriated as needed in construction. Plans can thus go forward at once for the construction of the new building. For the needs of the Survey and the other bureaus mentioned an up-to-date, conveniently arranged, and well-lighted building is of especial importance. Too many of the civil employees at Washington work in part or exclusively by artificial light, in quarters that may be compared to dungeons, a condition which is suggestive of medieval times, when the first requirement of castles was walls thick enough to resist the attacks of battering rams and catapults, or of the still more ancient period when huge, ornate pillars and columns were the fashion, regardless of the arrangements with respect to light and convenience on the inside of the building. The innovation of providing a structure of the modern office type for government "workshops" in which a maximum of the best work is the first consideration, such as will occupy the new building, will be welcomed.

Mr. Alfred H. Brooks, of the Alaska Division, Mr. Sledge Tatum, of the Topographic Branch, and Mr. Herman Stabler, of the Water Resources Branch, of the Geological Survey, have been appointed an advisory committee to assist the director in regard to the plans for the new building.

#### SCIENTIFIC NOTES AND NEWS

For the meeting of the British Association, which will take place in Birmingham on September 10-17 next, under the presidency of Sir Oliver Lodge, F.R.S., the following sectional presidents have been appointed: A (mathematics and physics), Dr. H. F. Baker, F.R.S.; B (chemistry), Professor W. P. Wynne, F.R.S.; C (geology), Professor E. J. Garwood; D (zoology), Dr. H. F. Gadow, F.R.S.; E (geography), Professor H. N. Dickson; F (economics), Rev. P. H. Wicksteed; G (engineering), J. A. F. Aspinall, M.Eng.; H (an-

thropology), Sir Richard Temple, Bart., C.I.E.; I (physiology), Professor F. Gowland Hopkins, F.R.S.; K (botany), Miss Ethel Sargent, F.L.S.; L (education), Principal E. H. Griffiths, F.R.S.; M (agriculture), Professor T. B. Wood.

THE following fifteen candidates have been selected by the council of the Royal Society to be recommended for election into the society: Professor V. H. Blackman, Dr. William Bulloch, Mr. D. L. Chapman, Professor W. E. Dalby, Dr. T. R. Elliott, Professor J. C. Fields, Dr. J. S. Flett, Professor J. P. Hill, Mr. A. R. Hinks, Professor F. Keeble, Professor A. Keith, Dr. K. Lucas, Professor O. W. Richardson, Dr. W. Bosenhain, and Mr. G. W. Walker.

THE university faculty of Cornell University passed on March 14 the following resolution:

WHEREAS Professor Willard C. Fisher, a distinguished alumnus and former fellow of the university, has been dismissed from the chair of economics and social science at Wesleyan University on grounds stated in the letters of January 27, 1913, exchanged between the president of Wesleyan University and Professor Fisher; therefore, *Resolved*, that the faculty of Cornell University extend to Professor Fisher greetings and assurance of regard, with the message that his *alma mater* still seeks to maintain and extend the spirit of liberality, toleration and loyalty to truth, illustrated by the principles and lives of its founders, Ezra Cornell and Andrew D. White.

ON May 3 the Duke of Northumberland will be installed as chancellor of Durham University in succession to the late dean of Durham. The following are among the honorary degrees to be conferred: D.C.L., Lord Rayleigh; D.Sc., Sir Archibald Geikie, P.R.S., Sir J. J. Thomson, F.R.S., Sir William Crookes, F.R.S., Sir William Ramsay, F.R.S., Sir J. A. Ewing, F.R.S., Sir T. O. Allbutt, and Professor E. B. Poulton, F.R.S.

THE Harris lecture committee of Northwestern University has announced that the Norman Waite Harris lectures for 1913-14 will be delivered by Dr. Edwin Grant Conklin, professor of zoology at Princeton University.

The general subject of his lectures will be heredity and eugenics.

DR. LLOYD MORGAN, F.R.S., has been appointed Herbert Spencer lecturer for 1913 at the University of Oxford.

DR. ERNST MACH, professor of physics at Vienna, celebrated his seventy-fifth birthday on February 18.

THE trustees of the Peabody Museum, Salem, Mass., have granted Professor Edward S. Morse a year's leave of absence from the directorship with full salary, in order that he may complete his revision of the New England Mollusca and prepare for publication his Japanese journals.

DR. OSKAR BOLZA, honorary professor of mathematics in the University of Freiburg, who was for eighteen years actively associated with the department of mathematics in the University of Chicago and who is still non-resident professor in that department, will give courses during the summer quarter of the present year.

PROFESSOR CHARLES LANE POOR, of Columbia University, has been given leave of absence for next year. Professor Edward Kerner will have leave of absence during the second half year.

AT the recent meeting of the American Breeders' Association, Dr. David Fairchild, of Washington, was elected president, and Professor W. E. Castle, of Harvard University, vice-president.

OFFICERS of the Association of American Medical Colleges elected at Chicago, on February 26, are: *President*, E. P. Lyon, St. Louis University; *Vice-president*, F. F. Westbrook, University of Minnesota; *Secretary-treasurer*, F. C. Zapple, University of Illinois.

EDWARD W. BERRY, of the Johns Hopkins University, has been elected a member of the Société Géologique de France.

DR. S. W. STRATTON, director of the United States Bureau of Standards, Washington, D. C., has been elected a member of the council of the Underwriters' Laboratories, Chicago, Ill. The council is made up of twenty-

two leading engineers and experts of the United States and Canada, who serve without recompense and supervise the technical work of the institution.

ARTHUR H. BLANCHARD, M. Am. Soc. C. E., professor of highway engineering, Columbia University, has been appointed by Governor Sulzer a member of the advisory commission on highways for the state of New York.

MR. ANDREW H. PALMER, A.B. (Minnesota, '08), A.M. (Harvard, '09), formerly research assistant at Blue Hill Meteorological Observatory, has been appointed magnetic observer in the department of terrestrial magnetism, Carnegie Institution of Washington.

THE Nantucket Maria Mitchell astronomical fellowship of \$1,000 annually has been awarded a second time to Miss Margaret Harwood, A.B. (Radcliffe, '07). Her residence at the Nantucket Observatory is for six months, the remainder of the year is spent in a larger observatory of her own choice. She has elected to continue her researches at the Harvard College Observatory during this semester.

ASSOCIATE PROFESSOR HERBERT E. SLAUGHT, of the department of mathematics in the University of Chicago, has recently become the managing editor of the *American Mathematical Monthly*—a journal for teachers of mathematics in the collegiate and advanced secondary fields.

On the suggestion of the high commissioner for Cyprus, Sir Ronald Ross is this month visiting the island to investigate the causes of the prevalence of malarial fever.

THE Costa Rica-Panama Boundary Commission, of which Professor John F. Hayford, of Northwestern University College of Engineering, is chairman, is now in session at Northwestern University, compiling the results of the survey and investigations made a little over a year ago to settle the boundary dispute between the two countries. The commission was appointed by Chief Justice White, and the case will be argued before him as soon as the maps and information are complete. Director Hayford is also engaged in a

commission for the Carnegie Institution, the result of which is to determine the amount of evaporation of the five great lakes.

THE geological museum of Harvard University is sending G. C. Curtis to Hawaii to collect data for a naturalistic model of Kilauea. Kilauea crater lies within the proposed, and recently surveyed, U. S. National Volcano Park, where the Massachusetts Institute of Technology has recently erected an observatory. Mr. Curtis is the first American geologist to specialize in land relief and has during the past fifteen years brought a new motive and standard into American work. The model of Kilauea will be 12 feet long on the scale of 1:1500, and Museum Curator Sayles expects it to be unique in the contributions to the study of volcanoes.

PROFESSOR JOSEPH S. AMES, director of the physical laboratory, Johns Hopkins University, delivered an address on "Modern Views of the Structure of Matter" before the Science Club of the University of Wisconsin on March 4, 1913.

DR. GEORGE A. DORSEY, curator of anthropology in the Field Museum of Natural History, lectured before the Geographical Society of Chicago on March 14, his subject being "An Ethnologist Abroad."

PROFESSOR C. C. THOMAS, of the University of Wisconsin, lectured on March 6 at the University of Illinois on the subject "Marine Engines." The lecture was one of a series of exchange lectures arranged between the two universities.

DR. F. K. CAMERON, of the bureau of soils, U. S. Department of Agriculture, lectured before the Phi Lambda Upsilon Society at Columbia University on "The Solution of the Potash Problem in America," on March 6.

G. WILLIS MOORE, chief of the Federal Weather Bureau, lectured at Oberlin College on March 12, on "The Story of the Air."

SIR RICKMAN J. GODLEE, president of the Royal College of Surgeons, gave, on March 13, the foundation oration before the University College Union Society on "Lister and his Work."

It is stated in *Nature* that an exhibition of works by the late Mr. Thomas Woolner, R.A., has been opened at his studios. The exhibits include a number of objects of interest to men of science, among them being plaster busts of Charles Darwin, Huxley and Richard Quain, bronze medallions of Darwin and Sir Joseph Hooker, a colossal head, in plaster, of Captain Cook, and a bronze medal representing science and research. Any works not disposed of during the exhibition will be sold in the studio by auction.

MR. WILBUR WRIGHT bequeathed \$50,000 to each of his brothers, Rauchlin Wright and Loring Wright, and to his sister, Katharine Wright. His other property he left to his brother, Orville Wright, "who has been associated with me in all the hopes and labors both of my childhood and manhood, and who will, I am sure, use the property in very much the same manner as we would use it together, in case we should both survive to old age; and for this reason I make no specific bequest to charity."

PROFESSOR ADAM SEDGWICK, F.R.S., formerly professor of zoology at the University of Cambridge, and since 1909 in the Imperial College of Science, London, has died at the age of fifty-seven years.

SIR WILLIAM ARROL, the distinguished British bridge builder, died on February 20, at the age of seventy-four years.

MR. GEORGE MATTHEY, F.R.S., who, while actively engaged in commercial work, made experiments in scientific metallurgy, died on February 14, aged eight-seven years.

DR. M. M. MCHARDY, late professor of ophthalmology in King's College, London, inventor of the registering perimeter which bears his name, died on February 8, at the age of sixty years.

PROFESSOR W. TAIT, in charge of chemistry in the civil engineering college at Sibpur, near Calcutta, died on February 19.

M. ALFRED MAURICE PICARD, the eminent French engineer, member of the Paris Academy of Sciences, died on March 8, aged sixty-nine years.

THE death is announced of Professor William H. Lennon, for forty-two years head of the department of science in the Brockport State Normal School, New York.

PHI LAMBDA Upsilon, the honorary chemical society, will hold its biennial convention at Milwaukee, Wis., March 24 and 25, just preceding the meeting of the American Chemical Society. The headquarters for the convention will be the Hotel Pfister.

THE regents of the University of Wisconsin have voted to extend an invitation to the Association of American Agricultural Colleges and Experiment Stations to hold a four-week graduate school in agriculture and home economics at the university, in July, 1914.

THE German Association of Engineers is making preparations for the reception of the American Society of Mechanical Engineers, which will hold its annual meeting this year in Leipzig. The Americans will arrive at Hamburg on June 19. Following the meeting they will make a fortnight's tour of Germany.

THE twenty-second session of the Marine Biological Laboratory of Stanford University, will begin Tuesday, May 27, 1913. The regular course of instruction will continue six weeks, closing July 8. Investigators and students working without instruction may make arrangements to continue their work through the summer. The laboratory, which is at Pacific Grove, will be under the general supervision of Professor F. M. McFarland, instructor in charge.

A CONFERENCE on the Conservation of Human Life will be held at Reed College, Portland, Oregon, on May 9, 10 and 11, 1913. There will be lectures, discussions, exhibits, moving pictures, out-of-door games and meetings of societies. All organizations and individuals devoted to human welfare are invited to take part in the conference. Fifteen rooms are available for the exhibits and fifteen rooms for meetings of such organizations. Three assembly rooms are equipped for stereopticon exhibitions. The following topics suggest the

scope of the conference: Organized efforts to abolish war, venereal diseases and child labor; to obtain pure foods, to prevent tuberculosis, to promote temperance, to improve conditions of labor, to safeguard men at sea and on railroads, to improve country life conditions, to better the living conditions of prisoners, juvenile offenders and other defectives, to prevent contagion, to curb occupational diseases, to solve the housing problems of cities, and the health problems of immigration, to promote school hygiene, playgrounds and recreation centers.

THE coroner of Cook County, with headquarters in Chicago, is about to establish a chemical laboratory, primarily for toxicological chemistry. The salary of the chemist in charge will be \$2,500 per annum, and there will be one assistant. The work will be directed by an advisory committee consisting of Hon. Harry Olson, chief justice, Municipal Courts of Chicago; Professor John H. Long, professor of chemistry, Northwestern University Medical School; John A. Wesener, M.D., Columbus Memorial Laboratory; Ludvig Hektoen, M.D., director, Memorial Institute for Infectious Diseases; Professor Walter S. Harnes, professor of chemistry and toxicology in the University of Chicago and Rush Medical College. Applications may be sent to Peter M. Hoffman, coroner, Room 500, County Building, Chicago, Illinois.

THE Field Museum of Natural History announces its thirty-eighth Free Lecture Course as follows:

March 1—"A Look into South America," Professor Rollin D. Salisbury, the University of Chicago.

March 8—"Fossil Collecting," Mr. A. W. Slocom, assistant curator, Division of Invertebrate Paleontology.

March 15—"Cultural and Somatic Evidences of Man's Antiquity," Professor George Grant MacCurdy, Yale University.

March 22—"Spain: Country and People," Mr. Arthur Stanley Riggs, New York.

March 29—"Newfoundland," Professor M. L. Fernald, Harvard University.

April 5—"Wild Flowers of the Chicago Region," Dr. C. F. Millsbaugh, curator, Department of Botany.

April 12—"Crossing the Andes of Northern Peru," Mr. W. H. Osgood, assistant curator of mammalogy and ornithology.

April 19—"Logging California Redwoods," Mr. Huron H. Smith, assistant curator, Division of Dendrology.

April 26—"Religious and Artistic Thought in China," Dr. Berthold Laufer, associate curator of Asiatic ethnology.

LINCOLN HALL at the University of Illinois was formally dedicated "to the study of the humanities, in memory of Abraham Lincoln, and in the name of the people of Illinois" on Lincoln's birthday, February 12. Representatives from many American educational institutions were present. Addresses on the importance to the commonwealth of adequate provisions for the study of the humanities were made by Professor Bliss Perry, of Harvard University; Dean Frederick J. C. Woodbridge, professor of philosophy at Columbia University, and by Dr. Albert Shaw, editor of the *Review of Reviews*. Bishop Wm. F. McDowell, of Chicago, conducted the ceremony of dedication, and addresses were made by the governor of the state, the president of the board of trustees, the state architect and the president of the university. Dr. Hugo Black, of Union Seminary, New York, spoke on "How Lincoln Appeared to a Scotchman." The sum of two hundred and fifty thousand dollars was appropriated at the session of the Illinois legislature beginning in January, 1909, the hundredth anniversary of Lincoln's birth, for a building to be dedicated to the study of humanities. It was decided to make this building a memorial to Abraham Lincoln, the first citizen of Illinois to be elected president of the United States, the signer of the bill which made the state university possible and the consistent and persevering friend of higher education in state and nation. The scheme of decoration includes a series of

memorial panels, tablets, medallions, inscriptions, etc., relating to Lincoln and his times, so that students and professors at work in this building, or even passing along the walks about it, should be in daily and hourly remembrance of what this man and his coworkers did for the American people. Quarters are provided on the first floor for the classics and for the philosophical group or department; on the second floor, for English and modern languages; and on the third floor, for the social science group, comprising history, economics, politics and sociology. The north and south wings of the fourth floor are set apart for two museums. The museum of classical archeology and art comprises collections designed to show especially the influence on our American life of the fine arts of the Greeks and Romans, particularly sculpture and other forms of antiquities, by means of casts, photographs and original articles. The second museum, the museum of European culture, occupies the north wing of the building and contains much illustrative material. The museum of classic art was opened on November 8. Professor George Henry Chase, of Harvard University, delivered the dedicatory address. The museum of European culture was opened February 6, at which time Professor Kuno Franke, of Harvard University, delivered two addresses.

#### UNIVERSITY AND EDUCATIONAL NEWS

JAPANESE graduates of Harvard University have subscribed a fund of \$20,000 as the foundation for a lectureship in the department of philosophy to provide for the teaching of Japanese and other Oriental systems of philosophy.

ON March 6, the University of Illinois opened a medical college in Chicago. The property formerly belonging to the College of Physicians was definitely presented by the alumni to the university. It is valued at \$500,000 with an indebtedness of \$245,000. Twice the state legislature by a large major-

ity has appropriated money for a medical school in connection with the university. The first time the bill was vetoed by the governor because of lack of funds, the second time the bill was thrown out on a technicality. At the opening exercises addresses were given by Dr. Frank Billings, dean of Rush Medical College, by Dr. A. R. Edwards, dean of Northwestern University Medical School, by Dr. Arthur Dean Bevan, chairman of council on Medical Education, American Medical Association; by President E. J. James, of the University of Illinois; by Dean W. E. Quine and others.

THE plans for transforming the scientific institutes at Frankfort-on-Main into a university have now been sanctioned by the Prussian ministry of public instruction. The capital subscribed is nearly \$2,000,000.

DR. A. R. FORSYTH, F.R.S., has been appointed chief professor of mathematics at the Imperial College of Science and Technology, London.

MR. AUGUSTINE HENRY, M.A., reader in forestry at Cambridge, has been appointed professor of forestry in the Royal College of Science for Ireland. The chair of forestry at the college has but recently been established.

MR. ROBERT B. BOURDILLON, lecturer in chemistry at Balliol College, Oxford, has been elected to a fellowship in chemistry on the teaching staff of University College.

AT Sheffield University Miss Sophia M. V. Witts, M.D. (London), has been appointed to the newly-instituted post of "lady tutor in anatomy."

THE following appointments have been made in the department of public health at King's College, London: Dr. E. W. Routley, medical officer of health, Aldershot, to be lecturer in sanitary law and administration; Colonel W. G. King, late sanitary commissioner in the Madras Presidency, to be lecturer in applied hygiene in the tropics; Dr. W. F. Roach, to be lecturer on school hygiene for medical officers.

## DISCUSSION AND CORRESPONDENCE

## THE YELLOWSTONE

TO THE EDITOR OF SCIENCE: In a recent lecture before the students of Lehigh University describing a camping trip through the Wind River Mountains and through the Yellowstone Park during the summer of 1911, I exhibited a working model of a geyser which erupted about forty times per hour, and a working model of the curious Handkerchief Pool which is located in the Upper Geyser Basin about a mile west and north of Old Faithful Inn. Perhaps some of the readers of SCIENCE may be interested in the model of the Handkerchief Pool and the explanation of its action.

FIG. 1.

The eruptive action of a geyser is probably due, as Bunsen suggested, to the heating of the water at the bottom of a deep hole to a temperature much above  $100^{\circ}\text{C}.$ , and the consequent violent boiling of this over-heated water when the pressure is suddenly lowered by the blowing out of the water in the upper part of the hole. A small working model of the geyser can not conveniently be made on this principle. The principle of operation of the model geyser I used in my lecture is shown in Fig. 1, and the actual apparatus is shown in Fig. 2.

The principle of operation of the Handkerchief Pool is shown in Fig. 3. Hot water is pushed in a sudden pulse through a channel and through the small throat *TT* into a shallow pool *PP*, and the condensation of the driving steam causes a sudden backward suction through the throat. This action is repeated several times per minute, and the hot water in the shallow pool being cooled, flows

downwards at the edges of the pool and towards the throat as indicated by the arrows. Placing the handkerchief at the edge of this

FIG. 2.

pool it is carried towards the throat by the downward flow of cool water, and when it comes near the throat it is suddenly sucked out of sight into the chamber *C*. The impres-

FIG. 3.

sion is that one will never recover his handkerchief, but in the course of about half a minute the handkerchief is thrown violently out of *C* by an upward surge of hot water. If the handkerchief is left in the pool this behavior is repeated over and over again.

FIG. 4. Working Model of Handkerchief Pool.

In all probability the numerous small hot springs in the Geyser Basin and perhaps also at Mammoth Hot Springs come from jets of

steam which are condensed near the surface of the rock and the condensed water collects in small pools from which it flows in a small stream. The hot springs at the lower levels may be genuine streams of water flowing from great depths, but it is inconceivable that they should originate in one connected body or stream of water.

Tourists who camp in the Park are called "sagebrushers," and if you wish to excite the indignation of a "sagebrusher" talk to him about Yellowstone Park bears! One or two bears feeding at each hotel garbage dump would be sufficient for tourists; but at present bears congregate at the various hotel garbage dumps to the number of fifteen or twenty at a time, and the cleaning out of sagebrushers' camps by marauding bears is a nightly occurrence. The one all-absorbing topic of conversation among sagebrushers is marauding bears; and it is by no means a joke, for three or four sagebrushers are killed nearly every summer in attempting to drive bears out of their camps! The Yellowstone Park bears are an unmitigated and intolerable nuisance, and nine tenths of them should be killed at once. The only alternative is for the Park authorities to establish a vigilant all-night watch around every camping ground.

One of the points of interest at Mammoth Hot Springs is a grotto, a cavity in the hot-springs formation, and tourists are taken into this grotto in parties of twenty or thirty at a time. Only one hundred yards or so from the grotto is an opening through which carbon dioxide issues, filling a small depression at the bottom of which two or three dead birds are usually seen. If a crevice should be opened up from the grotto to any of the old hot-water channels, the grotto would in all probability be filled with carbon dioxide, and the next party of tourists would be left at the bottom of the grotto like the birds in the little valley near by. It would be wise on the part of the park management to provide for a test of the air of the grotto every morning during the tourist season. If this is not done a disaster is likely to occur at any time.

At Mammoth Hot Springs Hotel I wished

to purchase a number of large colored views and I naturally went to the "official photographer of the park." The next day, however, I found a better grade of pictures for sale at an outside place and at a cheaper price, and to my disgust I found that the colored views I had purchased from the official photographer were of foreign manufacture, whereas the cheaper and better ones which were sold by the unofficial photographer were of American manufacture! Surely the position of official photographer should be done away with in the Yellowstone Park. Very certainly it is not right for the public to be led by the term "official photographer" to purchase foreign-made colored views which are more expensive than American-made views and at the same time distinctly inferior.

Any one who has traveled through the region to the south and east of the Yellowstone Park must realize what a splendid game preserve we could have if the Yellowstone Park were extended to the east so as to include the Absaroka Mountains and to the south so as to include Jackson's Hole and Teton Mountains and Gros Ventre Mountains. The private holdings of land in Jackson's Hole could be purchased for a very moderate sum and the entire surrounding mountain region is already included in the National Forest Reserves. It would be a very easy matter for the national government to greatly extend the boundaries of the Yellowstone Park and create what would be perhaps the most magnificent asylum for wild animals in the whole world.

W. S. FRANKLIN

#### ALLEGHANY VALLEY EROSION

TO THE EDITOR OF SCIENCE: In the recent issue of the *Bulletin* of the Geological Society of America, Vol. XXIII, p. 295, is the paper of G. F. Wright on "Postglacial Erosion and Oxidation." In the summary of the discussion which followed, the reporter states that Mr. Leverett offered as disproof of the conclusions of Professor Wright the "great erosion in the upper Alleghany region which occurred between the deposition of the old drift and of the young or Wisconsin drift."

Here is a general statement that there is an "old" and a "young" drift in the "upper Alleghany region," and that a "great erosion" occurred between their deposition. The generality of the statement would lead one to infer that the erosion was general throughout the region, and that this fact was generally received, as well as that there was such a distinction between the "old" and "young" drifts that they could be readily differentiated everywhere by physical characteristics.

In discussing this statement we must first ascertain what Mr. Leverett considers "the upper Alleghany region," as the river is a long one. Happily we have in the map compiled by Mr. Alden for the Geological Survey a very plain demarkation of areas variously estimated by Mr. Leverett. In the above discussion he uses the term "old" drift, referring to the first or Kansan advance. Combining this statement with the areas of the map we arrive at the conclusion that the uppermost portions of the Alleghany region to which he can possibly refer begin in the immediate vicinity of Warren, Pennsylvania, which is about 100 miles from the source of the river, as above that place the river is marked as flowing through areas not reached by Kansan ice. The terms Kansan and Wisconsin are used to define alleged earlier and later phases of glaciation separated by a long interval. We will, therefore, discuss the conditions of this system from Warren southward; but as there is no method of estimating where Mr. Leverett's term "upper" ends, we will continue our discussion to and below Parker, which is half way between Warren and Pittsburgh.

After Lewis and Wright published the volume of the Second Geological Survey of Pennsylvania delimiting the "terminal moraine," Carll, in his report of the Warren region, called attention about thirty-five years ago to the preglacial channel of the Conewango now deeply buried throughout in drift which rose near Kane and flowed westward through Sheffield, Clarendon, Stoneham and Glade, between which place and Warren it crossed the present channel of the Alleghany

and flowed north into the St. Lawrence drainage system. On the northern bank of this stream and over 100 feet above its present level is a remnant of Mr. Leverett's "old drift." Between the time of its deposition and the excavation of the wide valley to present level he imagines that a long period has elapsed, and this excavation is his "great erosion." At Clarendon is more of his "old drift," also at Franklin; also at Parker. Bradford, being above Warren, is in the unglaciated area. The distances apart of these places are: Bradford to Warren (along the valley lines), 60 miles; Warren to Franklin, 60 miles; Franklin to Parker, 35 miles; Kittanning is about 25 miles below Parker. These distances enable us to employ the rule which obtains in geology as well as geometry, that when a number of points in a line or plane sufficiently distant from one another have been referred to a given datum plane, the portion of the line or plane included between those points has also been referred to the same plane. The datum plane in this case is the present drainage level of the Alleghany, and to it we will refer both the underlying rock bottom and the "old drift" of Mr. Leverett.

Our data for reference exist abundantly, as the region had been pierced from surface to great depths by tens of thousands of oil wells whose sections have been recorded, and many have been published. These wells are found in numbers on the "old drift," the "young drift," the mountain tops, the swamps and the river beds, and where rock was not near the surface a pipe was driven through the loose deposits till rock was struck. These "drive-pipe" records show the materials passed through, and form a valuable and conclusive array of facts beyond the possibility of cavil or argument.

The problem for discussion is the probable form and sequence of deposits over a region deeply flooded by an approaching but still distant glacier which forced the waters over a still more distant col which was gradually degraded. Every prospector and ore-dresser is well acquainted with the classifying and

sorting powers of streams of varying velocities, and nothing could more plainly show the distance of the glacier and the stagnation of the water than the varying thicknesses of clean sticky clay which universally lie against the rock floor of the region. Where bays to one side of the line of current offered especially still water its thickness runs up to 100 feet. Even on the hillside at Warren near the "old drift" and not far above present water level the writer has found it and taken fragments of wood therefrom. This presence of the broken pieces of the old forest in the clay is proof of a first invasion of the region, and at Bradford, Clarendon, Stoneham and elsewhere outside of the area of discussion the heaps of accumulated logs were so well preserved as to make the driving of the pipe to bed rock a most difficult operation. Even as far down the river as Kittanning this clay is so abundant as to furnish material for the manufacture of china. Above this the sequence of deposits is a fine quicksand resembling a friable clay; a coarser quicksand; sands, and, finally, gravels. Where there was continuous current action the lighter varieties are generally absent, and where it swept along one side of a valley with torrential force even the gravels are absent on that side, as at Warren, Franklin, Brandon, Kennerdell and numerous other places not noted in the many discussions of this region. At Bradford, Stoneham and Clarendon we have the whole series as it was laid down, as shown by the thousand wells of Bradford, the hundreds at Stoneham, and the 1,300 or more of the South Pennsylvania Company about Clarendon.

Regarding the alleged "old gravels" which are supposed to have been laid down in a river bed whose bottom was several hundred feet above present water-level, we find that they vary in level A.T. 100 feet or more within a few miles and around the shoulders of the same hill. Streams never run up hill and so there was no stream deposition at such places.

Coming from generalities to specific localities we find at Bradford, outside of the so-called Kansan area, that the valley for miles has a nearly flat surface, and the rock floor

averages 200 feet below it. Taking the Clarendon-Stoneham-Glade-Warren rock floor of Carll's preglacial stream we find the drive pipes at the first place will run from 200 to 310 feet. The last was located on and ran through Mr. Leverett's "old drift." At Stoneham the average is 200 to 232 feet: at Glade, 100 feet; at Warren, and again on the "old drift" are several wells which place the rock floor on a slope running from present water level to fifty feet below it. The averages of the four localities above given show that the floor dips from Clarendon to Warren and will average 1,200 A.T., or below present water-level. This being the fact, the "old drift" patches are shown to be the youngest of a regular series, and as the rock floor level was determined before deposition began, there has been here no "great erosion." For 60 miles of the valley we can say "no erosion."

At Franklin we find rusty gravel on the hillside north of French Creek. The new water works enabled the writer to inspect a deep trench for the city mains which ran from just above water-level to several hundred feet up the mountain, where the reservoir was being built. As the trench went down to soil rotting in place there was a chance to see the soil line and to note that the sediments were washes parallel thereto, and carrying the same amount and kinds of foreign rocks throughout all elevations exposed. Here also the "old drift" lay on top of the wash, and there was no "erosion."

Parker was made much of, as here was an alleged "abandoned loop" of a mythical Alleghany of Kansan times. The writer showed, more than a dozen years ago in *SCIENCE*, that the wide difference in elevation, material and dip of the deposits precluded their being laid down by a stream, and this was proved by the usual oil well not very far from the Alleghany which went down through the "old drift" to below the present water level.

We have now performed our task, the reference of the "old drift" at Warren, Clarendon, Franklin and Parker to the present water level, and in all these places it lies over the old bottom as the uppermost of a regular

series laid thereon, showing conclusively that the bottom was leveled preglacially and that there has been no "erosion."

In view of these facts, which anybody can check, it is germane to the subject to ask Mr. Leverett to kindly be specific and state exactly where this "great erosion" occurred over the "upper Alleghany region."

EDWARD H. WILLIAMS, JR.

#### ACADEMIC FREEDOM

TO THE EDITOR OF SCIENCE: The dismissal of Professor Willard C. Fisher from the chair of political and social science at Wesleyan University, which has now been made formal and definitive by the acquiescence of the trustees in the action of the president, is an occurrence that shows the need of constant effort and discussion in order to maintain the right of freedom of speech and of teaching. The correspondence between President Shanklin and Professor Fisher, as published in a recent number of SCIENCE (February 14), is on its face sufficient evidence that a teacher who had served the institution for twenty years was summarily removed on grounds that are absolutely trivial and puerile. From various sources which seem reliable the report comes that Professor Fisher's address at Hartford was not the cause of his dismissal, but that the real ground is to be found in the objection felt by the president and some of the trustees of the college to his political and social views. If this is so, it only emphasizes the fact that there has been a serious infringement of the principle of academic freedom. The matter is too serious to be allowed to drop: it seems desirable that there should be protests from universities, learned societies and individuals so numerous as to arouse public opinion and render any similar occurrence impossible in the future. Physical science has fortunately no longer to fear any direct interference from outside authority. It is a long time since Galileo; and even the doctrine of evolution now calls out no protest from any quarter. But the representatives of these sciences will not fail to recognize that

their own cause is bound up with that of the economists and social philosophers who now furnish the chief grounds of offence to the "interests." For freedom of speech and of research can not be limited to certain subjects: science can not exist half slave and half free. I conclude by quoting an extract from an address of President Schurman as reported in the *Cornell Sun* for September 24, 1897, which seems to me a fine statement of principles of which we should never lose sight.

If it is asserted that the business of the college or university is to teach that which the average man may believe, or that which is acceptable to the university, or that which the board of trustees may assert as the truth, the answer must always be that such a course contravenes the very principle on which the university was founded, and however true it may be that the majority must rule in the body politic, the motto of the university must be, one man with God's truth is a majority. There is also a second principle involved in what has been said if all this be true. It is perfectly clear that every teacher must be free to carry out his inquiries and to announce and proclaim if he wishes what he has observed, or in dealing with the individual student the teacher must be free to present all phases of the question as they occur to him—otherwise he has missed his great vocation as a teacher.

Money is needed by universities. I know it well. I know that our board of trustees is constantly wrestling with the problem of how to make both ends meet, how to meet the legitimate demands of the heads of departments and colleges, yet if money is to be got for the institution by the suppression of the truth, by setting any limitation whatever upon the freedom of the teachers to inquire or to announce the results of their inquiries, better a thousand times that the institution should go out of existence. The end of a university is truth and the promotion of truth. Money may be a means to that end, and as a means it may kindle a great light; as an end it can only produce total darkness. Hence any attempt to set limitations upon the independence of the teaching staff must be resisted, must be unwarranted. We need for the advance of civilization the striking out of new ideas or the application of old ideas to new fields. Where are such ideas to be urged, if the business of the university is to teach what is acceptable to the community? All science would be impossible on this theory.

It was perhaps more than a coincidence that this address was delivered soon after the resignation from Brown University of President E. Benjamin Andrews.

#### SCIENTIFIC BOOKS

*The British Tunicata.* An Unfinished Monograph by the late JOSHUA ALDER and the late ALBANY HANCOCK, F.L.S. Edited by JOHN HOPKINSON, F.L.S., F.G.S., etc., Secretary of the Ray Society, with a history of the work by the Reverend A. M. NORMAN, M.A., D.C.L., F.R.S., etc. Volume I, 146 pp., 20 pls., 1905; Volume II, 162 pp., 50 pls., 1907; Volume III, 90 pp., 66 pls., 1912. The Ray Society.

With the appearance during the last year of a third volume of Alder and Hancock's researches on British ascidians all that is to be printed of this magnificent work is now available to students. The earlier volumes have been duly noticed by reviewers as they were distributed; but for the sake of completeness it will not be amiss to speak of all three volumes together.

The task of selecting and preparing the manuscript and illustrations must have been both perplexing and laborious, for we are told by Canon Norman in his history of the work which introduces the first volume, that the drawings, particularly those by Hancock, are very numerous and in many stages of completion. The bracketed words, sentences and paragraphs scattered all through the text testify to the extensive and painstaking work performed by Mr. Hopkinson.

Very wisely not much has been added to or subtracted from the work as it left the hands of the authors. The diagnoses of species of the compound ascidians have received more editorial modifications than have those of the simple ones. In a few instances species and genera have been included which did not appear as such in the manuscript, but only where the notes and sketches warranted.

The part played by Canon Norman in bringing the work to the light of day was un-

doubtedly done under the stimulus of personal devotion and direct scientific interest, his friendship for and association with the authors having been intimate and of long standing, and he contributed much, particularly in the way of specimens, to the substance of the monograph. Mr. Hopkinson's rôle seems to have been solely that of an official and a man of science, and what he has done is a fine testimonial to his ability in this way.

Volume I. contains, as mentioned above, a review of the origin and vicissitudes of the work, by Canon Norman; an introduction by the authors; a reprint of Hancock's "On the Anatomy and Physiology of the Tunicata" originally published in the *Journal of the Linnean Society of London* in 1867; and the systematic treatment of all the species of the genus *Ascidia*. Volume II. opens with a life of Alder by Norman, and of Hancock by Embleton, and deals with the remaining genera, *Ciona* and *Corella*, of the family Ascidiadae, and the families Molgulidae, Cynthiadae, and Clavelinidae. Volume III. treats of the "Aggregatae," of which three families, Polyclinidae, Didemnidae and Botryllidae, are recognized, and ends with a supplement by Mr. Hopkinson containing "Additional References and Localities"; a "List of the Species described in the Monograph, with the Genera under which they would probably now be placed," and a "General Index."

There can be no question about the value of this monograph, even though it represents the state of knowledge of ascidians as it was forty years ago, and makes no pretense of concerning itself with other than British species. Its chief utility will naturally be as a handbook for British students and other persons who frequent the shores of the British islands. The great number and excellence of the illustrations, particularly those of habitus of the kinds, "forms," varieties and species, mostly by Alder, will make it specially useful in this way. Nearly all the figures, even the anatomical ones from Hancock's faithful brush, are in color. The authors evidently devoted much less time to the compound than to the simple species; and for illustrating

these the editor has largely supplemented the original drawings from figures by Savigny and Milne Edwards. But the usefulness of the book will be by no means restricted to students who are countrymen of the authors. It will undoubtedly take a conspicuous place in the working library of specialists in the group wherever located, as it already has in that of the reviewer.

Divers reflections are induced by reading the divers things said in these volumes by divers persons. The brief, straightforward account by Canon Norman in Volume I. of how the monograph came to be undertaken relates that Alder was requested by the keeper of the zoological department of the British Museum to prepare a "Catalogue of British Tunicata" as one of the series of catalogues then being issued by the Museum; that Alder at once took up the task and pushed it to the exclusion of everything else; and that after several years' work when he reported the manuscript ready to be turned in he was informed by the keeper (with the deepest regret) that somebody had withdrawn the grant for publishing the catalogues, and that consequently his work could not be published. In the absence of information to the contrary this looks like a flagrant breach of contract on the part of the Museum, and reminds one of the frequent charge that institutions and governments hold themselves less bound by contracts than individuals are supposed to be held. If this be so the fact can only mean that communities in which it is true are still in an immature stage of advancement in civilization, so that as time goes on and with it progress it will be impossible for such cases of broken faith to occur.

The extent to which embryological knowledge may modify interpretations based solely on anatomical knowledge could hardly be more strikingly illustrated than by Hancock's ideas about the homologies of tunicate organs. He knew almost as much as we of to-day know about the gross structure of full-grown ascidians, yet he considered the close kindred of the group with the polyzoa to be fully established! The proposal made by several zoologists to

separate the ascidians from the molluscs he looked upon with great disfavor, and his efforts to prove the resemblance between the respiratory apparatus of an ascidian and that of a bivalve mollusc seem curious enough to us now. Of course he was familiar with the tadpole stage of the individual ascidian, though he thought it a secondary acquirement. But it is not alone with reference to these broad generalizations as to group affinities and classification that discoveries in development have changed morphological ideas. There is hardly a page of Hancock's essay that does not contain some interpretation, expressed or implied, which does not accord with present views. Kowalevsky's epochal "*Entwicklungsgeschichte der einfachen Ascidien*" was published in 1866, and although Hancock's "*On the Anatomy and Physiology of the Tunicata*" did not appear until the next year, there is no indication that the English comparative anatomists had read the memoir of the Russian embryologist.

In an addendum to the biographies of the authors which introduce the second volume, Canon Norman remarks that Alder and Hancock were "naturalists of a by-gone time." "With only very moderate advantages," he says, "as regards early education, they progressed greatly in knowledge by private study as years went by. An intense love of nature absorbed them, and they realized that everything else must be sacrificed to allow them to find out nature's secrets." When one recalls that these were only two among a considerable number of Britishers of that period who, largely self-trained, passed all or a great part of their lives in unremitting toil as investigators of nature, and did this without compensation or institutional aid, he can but be mindful how unqualifiedly true is Norman's remark about a by-gone age. Undoubtedly the refinements of method in nearly all departments of research, necessitated by the advancements that have been made, account in large measure for the almost entire disappearance of this type of scientific men. The professionalizing and institutionalizing of science in our day as compared with former days have

been, inevitably, both result and cause of the wonderful progress that has gone on. Surely there is neither possibility nor desire to return to the conditions of a half-century ago. But a certain quality or attitude of mind essential, according to the reviewer's notion, to the best achievements has been lost since the former days. Reference may be made to what some astronomer, Professor Hale I believe, has extolled as the amateur spirit in science: a spontaneous, perennial curiosity; a wide-awakeness of perception; an openness of mind; and a nimbleness of imagination, as touching all sorts of objects and processes and incidents in one's surroundings. The belief prevails widely among biologists of the present day that this sort of thing necessarily begets superficiality—that it is inimical to that profundity demanded by the deep, ultimate problems which constitute the soul of science. The belief is, however, not justified by either the history of scientific discovery, or our modern knowledge of the constitution and workings of the human mind. The "complex" of recent psychology is a "system of connected ideas with a strong emotional tone"; and specialization may go so far in both differentiation and intensification as to tend to reduce the system of ideas to one idea, and to destroy the "emotional tone."

Such works as the one now before us, taken in their entirety, ought to serve the two-fold end of helping on knowledge in a restricted field of zoology, and of restoring to biological research something of the amateur spirit.

WM. E. RITTER

*List of North American Land Mammals in the United States National Museum, 1911.*

By GERRIT S. MILLER, JR., Curator, Division of Mammals, United States National Museum. Bulletin 79, United States National Museum. Washington, Government Printing Office. 1912. 8vo. Pp. xiv + 455.

This volume is a most welcome contribution to mammalogical literature, giving, as it does, in systematic sequence, the names of the species and subspecies of all North American

land mammals currently recognized down to the end of the year 1911, and a large part of those described during 1912. "North America," for the purpose of the list, comprises "the entire continent from Panama northward, together with Greenland and the Greater and Lesser Antilles." It consequently includes the Island of Trinidad, which is, faunally and geographically, really South American. According to the author's tabular summary, the number of "forms" included in the list is 2,138, of which 1,955 are represented in the United States National Museum, leaving only 183 as unrepresented. The types of about one half of the total number of forms are in the National Museum.

The plan of the list is about as follows: The classification, or "sequence of groups is, in its main features, that adopted by Osborn in his 'Age of Mammals,' 1910, though the arrangement of the families and genera has been revised to make it as consistently as possible in harmony with that of the higher groups." References are given to the place of first publication of all generic, specific and subspecific names, and types are designated for the genera. In the case of species and subspecies, reference is usually made to the first use of the binomial or trinomial here adopted, and to True's list of 1885. "The type locality of each form is stated with all possible exactitude; and in revised genera the ranges are given as printed by the author," references to such revisions being given in footnotes.

The list includes: (1) species and subspecies that "had not been questioned in some recent work of definite monographic character" prior to the end of the year 1911; (2) forms belonging to groups which have not been treated in a monographic paper; and in cases where differences of opinion regarding their status have developed, "references are given to the conflicting views," at least in most cases. The utility of this work to investigators is further enhanced by an asterisk prefixed to the names of forms contained in the National Museum, and also a dagger in case the museum also has the type. The author has of

course expressed his preferences in deciding disputed questions of nomenclature, of which a few might well be referred to the International Zoological Congress for arbitration.

As already stated, the number of species and subspecies of North American land mammals is in round numbers about 2,150, without including a considerable number described late in the year 1912. The first enumeration comparable in geographic area with Mr. Miller's was published by True<sup>1</sup> in 1885, numbering 365 species and subspecies. This number, according to Miller and Rehn,<sup>2</sup> had increased by the end of the year 1904 to 1,450. Elliot, in 1905, in his "Check List of the Mammals of the Continent of North America, the West Indies and the Neighboring Seas,"<sup>3</sup> included 1,940 forms of land mammals, he listing a considerable number that have since, through the work of monographers, passed into synonymy. Doubtless when other groups are subjected to this ordeal many listed in the present check list will also lapse, so that the number now fairly entitled to recognition may be estimated at about 2,000. Probably many valid additions are yet to be made from parts of Central America now very imperfectly known.

The task of preparing the present list could hardly have fallen to more competent hands, and mammalogists owe a debt of gratitude to its author for the great aid it will be to them in their work. It is to be regretted, however, that so unusual and confusing a system of classification has been adopted, the scheme being based on specialization, the sequence of the higher groups being determined by the amount of their departure in structure from the most "primitive" or "generalized" mammalian type, and not on affinity or genetic relationship. The arrangement therefore will be

very confusing and unprofitable to nine tenths of the users of Mr. Miller's book, who have been led to suppose that the purpose of a system of classification designed for general use was to indicate, so far as possible in a linear sequence, the affinities of the animals classified. The classification here adopted may serve the purpose for which it was intended—an expression of the relative degree of specialization among the ordinal groups of mammals; but it is rather startling to the uninitiated to find the two ends of the series represented, respectively, by the Monotremes and the Cetacea, and the Primates flanked on one side by the Edentates and on the other by the Artiodactyls: In other words, to find an otherwise admirable check list of the mammals of a continent arranged in conformity to a scheme of classification which ignores genetic relationships and therefore is out of touch with current faunistic and systematic work on recent mammals.

J. A. A.

*General Chemistry of the Enzymes.* By HANS EULER, Professor of Chemistry in the University of Stockholm. Translated from the German by THOMAS H. POPE. New York, John Wiley and Sons. Pp. 323.

The chemical changes which are taking place continually in plants and animals fall, for the most part, under that branch of science which is called organic chemistry. It is characteristic of organic reactions that they proceed slowly, though their progress can often be hastened by the addition of small amounts of particular substances, the so-called catalysts. This property of hastening the speed of organic reactions by supplying an appropriate catalyst is wonderfully developed in living organisms, because the element of time is all-important to them. The catalysts which occur in organisms are given the general name of enzymes. In many cases they can be readily separated from the cells of the organism and they are accordingly considered to be organic chemicals, probably of complex composition, but without organized or cell structure. Up to the present time no one has succeeded in crystallizing or vaporiz-

<sup>1</sup> True, F. W., "A Provisional List of the Mammals of North and Central America and the West Indian Islands," *Proc. U. S. Nat. Mus.*, Vol. 7, 1884, pp. 587-611 (appendix, 1885).

<sup>2</sup> "Systematic Results of the Study of North American Land Mammals to the Close of the Year 1900," *Proc. Boston Soc. Nat. Hist.*, Vol. 30, pp. 1-352, December, 1901.

<sup>3</sup> Field Columbian Museum, Zool. Ser., VI., 1905.

ing an enzyme and therefore such a thing as a pure enzyme is now unknown. For this reason the chemical analyses of dried "enzyme preparations" signify little, because it is impossible to know what portion of the preparation is enzyme and what is impurity. Pending the discovery of some method for crystallizing enzymes this branch of their study is practically at a standstill. On the other hand, the study of the mode of action of enzymes and the influence of temperature, acids, etc., upon their catalyzing power is advancing rapidly and it is with this subject that Professor Euler's treatise deals. To quote from the preface, he "has attempted to review the more important facts of enzymology from a general standpoint and to fit them, as far as is possible, into their proper places in the fabric of general and physical chemistry." This book is the first in which an attempt has been made to describe this branch of science from the standpoint of theoretical chemistry and special credit is due Professor Euler for his excellent treatment of the subject. The following chapter titles may serve to give an idea of the contents of the book: Special chemistry of the enzymes, their physical properties, their activators and poisons, the chemical dynamics of enzyme reactions, the influence of temperature and radiation on enzymic reactions, the chemical statics of enzyme reactions, enzymic syntheses and the specificity of enzyme action. The work of translation by Mr. Pope has been very carefully done. The publishers are also to be commended for the quality of the printing and binding.

##### MITOCHONDRIA IN ASCARIS SEX-CELLS

DURING the course of preparation of a thesis for the Doctor's degree at the University of Pennsylvania, entitled "The Spermatogenesis of *Ascaris megalocephala* with special reference to the two Cytoplasmic Inclusions, the *Refractive Body* and the '*Mitochondria*'; their *Origin, Nature* and *Rôle* in Fertilization," the following observations were made:

The refractive body arises, as Marcus

(1906), Mayer (1908) and Romieu (1911) point out, by the fusion of the refringent vesicles while still in the vas—probably just before copulation occurs. The refringent vesicles arise from minute granules scattered here and there throughout the cytoplasm in the early growth period of the spermatocyte. These granules stain blue after the material is fixed in Benda's modification of Flemming's strong solution and stained in Benda's "Krystal Violet." This reaction is characteristic of true mitochondria. Granules staining exactly like these are found constantly in the nucleus of the spermatogonium, and these actually pass through the nuclear membrane into the cytoplasm of the spermatocyte. This blue staining material, or true mitochondria, is apparently derived directly from the chromatin because in several cases chromosomes in the spermatogonial nuclei were cut, showing the red-brown interior (the typical reaction to Benda's stain for chromatin) covered by a blue layer. Thus the refractive body is ultimately derived from the chromatin of the spermatogonium, and it is formed by true mitochondria; these are not only nuclear in origin, they are derivatives of the karyosome. They should, therefore, be called *karyochondria* to distinguish them clearly from the *plastochondria* (Meves) which are derived from the plasmosome of the spermatogonial nucleus.

The refractive body has but one function—namely, to feed the spermatozoon on its long and exhausting journey (by pseudopodial creeping) to the "entrance region" at the proximal end of the uterus. This is proven by the fact that many eggs are entered there by spermatozoa which have lost every trace of the refractive body; and further, by the fact that the decrease in size of this body takes place equally from all sides, showing that it is the surrounding layer of cytoplasm, and not the uterine epithelial cells, as all other authors maintain, which is the agent of its absorption. Not only is its axial symmetry maintained during the stages of degeneration while crowded between the epithelial cells, but also when lying amongst eggs far out in the

lumen of the uterus. So it is fed upon only by the sperm itself.

The nematodes should, therefore, be placed in Faure-Fremiet's (1910) fourth class of mitochondria-bearing sex-cells, in which these granules produce yolk.

Marcus, Mayer, Romien and Faure-Fremiet use the term mitochondria to describe minute plastin granules found in the nucleus of the spermatogonium and in both nucleus and cytoplasm of the spermatocyte. They are easily seen in the "perinuclear zone" of the spermatid and in the "crown" of the spermatozoon. But nowhere do these granules take Benda's Krystal violet stain or transform into any cell structure. Hence they have no relationship with true mitochondria. Meves recognizes their nature and origin and calls them *plastochondria*. Van Beneden called them "protoplasmic corpuscles"; Altmann, "microsomes"; Boveri, "archoplasm." But none of these observers attributed any importance to them as bearers of hereditary characters. Meves (1910), however, finds (like the brothers Roja, 1891) that these granules fuse with similar ones in the egg after fertilization occurs, and he believes, with only this observation as a basis for it, that these *plastochondria* are the bearers of paternal structural characteristics. I have carefully studied the origin and behavior of these granules throughout the spermatogenesis and find that they everywhere behave, like the plasmosome itself, as if they were waste products of the metabolic processes of the chromatin. Many of them are actually thrown off by the spermatid with the cytoplasmic lobe, not only in *Ascaris*, but in many other forms. They always take plasma stains, yellow after Benda, and red after Ehrlich-Bionde, both reactions characteristic of secretions; they are pulled about in the cell by the force of the centrosomes to form aster rays and spindle fibers of the cleavage figure; they never divide, nor grow except by fusion on actual contact; in short, they behave everywhere as inert formed products only.

I believe that the observed facts of artificial

parthenogenesis, hybridization and fertilization of enucleated eggs, all argue against Meves' interpretation of the rôle of the *plastochondria*; while these facts and the observations of Baltzer, Tennant and others show clearly that it is the retention or elimination of chromatin (or the *karyochondria*) that determines the inheritance of paternal characters, segregation and dominance.

EDWARD E. WILDMAN

THE AMERICAN ASSOCIATION FOR THE  
ADVANCEMENT OF SCIENCE  
SECTION E—GEOLOGY AND GEOGRAPHY

The sixty-fourth meeting of Section E, Geology and Geography, of the American Association for the Advancement of Science, was held in the geological lecture room, main building, Case School of Applied Science, December 30, 1912, to January 2, 1913. Vice-president James E. Todd presided. The address of the retiring Vice-president, Professor B. Shimek was given on the subject, "The Significance of the Pleistocene Mollusks." Much interest was taken in the papers, which are here given with abstracts:

*Esker Terraces in Ohio*: G. FREDERICK WRIGHT.  
*The Wisconsin Drift-plain in the Region about Sioux Falls, S. D.* (illustrated): J. ERNEST CARMAN.

The region considered lies to the south of Sioux Falls along the line between Lincoln and Minnehaha counties, South Dakota. Professor Todd and others have interpreted it as belonging to the Wisconsin drift-plain, being an eastward projection of the James River lobe to the Big Sioux Valley. Professor Shimek has recently decided that the region is a Kansan drift-plain and not Wisconsin. The present paper describes the characteristics of this plain north and west of Shindlar and compares it with the typical Kansan region to the north and east. The evidence, chiefly physiographic, indicates that the region is a Wisconsin drift-plain. The conclusions of the paper support, in the main, the earlier interpretation of Professor Todd.

*The Pleistocene Succession in Wisconsin*: SAMUEL WEIDMAN.

A brief statement is given concerning present knowledge of the drift and associated surface deposits in Wisconsin, with a map showing distribution of the formations. There appear to be

five drift sheets exhibited in Wisconsin, as follows: First drift, a very old, thin drift; second drift, a very old, thick drift correlated with the Kansan of northeastern Iowa; third drift, a relatively old, thin drift, correlated with the Iowan of northeastern Iowa; fourth drift, a relatively thin, fresh drift, correlated with the early Wisconsin of northeastern Illinois; fifth drift, the Wisconsin drift. Extensive alluvial and lacustrine deposits in old valleys and lowlands, of interglacial origin between the second and third drifts. The loess deposits are of later origin than the third drift and older than the fourth.

*The "Moraines" of Kansas:* J. E. TODD.

Certain bouldery hills have been designated as glacial moraines by several writers on Kansas geology. This paper discusses their locations and relations to the former Kansan Ice sheet and present lines and levels of drainage and shows that they are not true moraines but river-laid deposits.

*Traces of an Early Wisconsin Flood:* J. E. TODD.

Attention is called to a deep silt which fills portions of the valleys of the Missouri and Kansas rivers in eastern Kansas, and which can not be correlated with the loess, because of its lower level. Because of evidences of the excavation of the valley so filled during and after the Kansas stage of the ice, it is argued that the date of the deposition of the silt was coincident with the recession of the Early Wisconsin Ice, or more definitely after the formation of the Altamont, or first marginal moraine. This lower loess or terrace silt is further provisionally correlated with terraces along the Missouri further north and its tributaries in western Iowa.

*The Sangamon Interglacial Stage in Minnesota:* WARREN UPHAM.

Three chains of lakes on the till area of Martin County, one of the central counties of the southern tier in Minnesota, adjoining Iowa, are ascribed to interglacial erosion of rivers flowing south, where now the courses of drainage pass eastward. The duration of this interglacial stage is estimated by Winchell, from changes of the course of the Mississippi River in and near the Twin Cities of Minneapolis and St. Paul, to have been about 15,000 years. It seems to be represented in the history of the Quaternary lakes Bonneville and Lahontan by the stage of their desiccation between their previous prolonged stage of high water and their ensuing higher but more brief rise of water; and it is correlated with the Sangamon inter-

glacial stage between the Illinoian and Iowan stages of glaciation. Its time is estimated to have been approximately from 40,000 to 25,000 years ago.

*The Relation of the Keewatin and Labrador Areas of Glaciation:* WARREN UPHAM.

The Kansan and Illinoian drift sheets are regarded as mainly of contemporaneous age. They were deposited respectively by the farthest southward extensions of the Keewatin and Labrador icefields. The belt of confluence of these icefields extended from the borders of the drift northward along or near the course of the Mississippi River up to the Wisconsin driftless area, which also reaches short distances into Illinois, Iowa and Minnesota. Beyond the driftless area, these Keewatin and Labrador currents of the continental ice-sheet were confluent along a belt or line passing north-northwesterly through Minnesota to the vicinity of Winnipeg, Manitoba and onward along the axis of Lake Winnipeg. At St. Paul and Minneapolis and northward, fluctuations of the line of confluence during the Wisconsin stages of glaciation produced extensive interbedding and sometimes a confused mingling of the Keewatin and Labrador drift formations.

*Types of Iron Ore in Tennessee:* C. H. GORDON.

Read by title.

*Criteria for Distinguishing Various Sorts of Common Deposits* (illustrated): A. C. TROWBRIDGE.

*The Age of the Mesabi Iron-bearing Rocks of Minnesota:* N. H. WINCHELL.

This paper gives a very brief summary of former opinion, and presents new evidence which goes to show that the Mesabi rocks are a part of the great Keweenawan formation.

*Angular Amphitheaters of the Grand Canyon:* CHARLES R. KEYES.

One of the most perfectly enigmatical features concerning the physiognomy of the Grand Canyon, in Arizona, and one to which little especial attention has been directed, is a certain regularity in the notably serrated character of the walls. Buttresses, reentrants and pyramids have a conspicuously rectangular ground-plan. So pronounced is this characteristic and so large is the scale that it is even emphasized in the latest contour-maps of the district. The angularities of the buttresses and pyramids are readily explained by the double system of master-joint structure. The deep reentrants or amphitheaters are not so easily disposed of, especially since all of the surface drainage, which is very deficient, of the general plateau

on either side of the canyon is directed away from the margin of the walls and not into the great trough. In some cases these reentrants are partially accounted for by the presence of faults trending transversely to the course of the river. In the majority of other cases the amphitheatres, great and small, appear to have originated through undercutting by differential wind action, the deflative effects being much more vigorous on the soft shales lying between the hard Carbonic limestones forming the upper wall and the hard granite floor of the inner canyon.

*Geologic Significance of Enisled Relief:* CHARLES R. KEYES.

Sharp meeting of lofty mountain and even plain, seemingly as level as the ocean strand-line, is one of the most characteristic features of desert landscapes. Foothills are also conspicuous by their absence. The very deficient rainfall of such regions can not possibly produce such topographic peculiarities. On the Mexican tableland, for instance, where the geologic structure presents a great thickness of soft later deposits, and the whole selberglandschaft of the Germans is probably more ideally perfect than anywhere else on the globe. A number of typical illustrations are described. The phenomena are best explained by the action of regional eolation, or general leveling and lowering of the country through deflation.

*Some Upland Flats in Jo Davies County, Illinois:* A. C. TROWBRIDGE.

An attempt to distinguish between raised peneplains, structural plains, plains of marine deposition and plains of marine erosion, in regions of nearly horizontal strata.

*The Value of Geochemistry to Geology and Geography:* J. CULVER HARTZELL.

The author stated that geology is the history of the earth, including organisms; geography is that part of geology which deals with the surface of the earth, and man in particular, and his relations to topographical, cultural, political and climatic environments. We are apt to forget the relations which the atmosphere, the hydrosphere and lithosphere bear to each other. Diastrophism, vulcanism and gradation are important; but the geochemistry is as important as the mechanics when changes in the equilibrium of chemical systems and their relation to man are considered. Atoms are different manifestations of one primal force. The farther we get away from *primal* the more distinct *chemical* and *physical* seem. There are pure and applied methods of procedure; but the

pure and applied principles are interdependent in the proper and accurate interpretation of facts. The value of geochemistry lies in the fact that it touches every division of geology in both its philosophy and its applicability. We need to get away from a sole contemplation of finished products. All forces are so balanced as to produce systems which are more or less stable; but which may be disturbed in such a way as to produce new systems which may in turn become more or less stable. These disturbances in equilibrium are as vital to the geologist as the system *per se*. We know a little about the balancing of forces; but the balancings are so multifarious as to be almost overwhelming, and it is only by careful, persistent investigation, interpretation and application of forces and the formulation of laws (perhaps tentative) that we can hope to know the genesis of any one system and its possible disturbance, thus accumulating a mass of data relative to many systems the final interpretation of which will make clear many of the heretofore apparently unsolvable problems. Stability, instability and disturbance cross our path and we must determine their relations. The atmosphere, hydrosphere and lithosphere were discussed. The reactions which take place, the manner and time of occurrence, the phenomena and the final results are the problems of the geochemist. The solution of these problems has a direct bearing on topographical, cultural, political and climatic effects as well as on diastrophic, volcanic and gradational effects. They also have a direct bearing on the igneous, metamorphic and unconsolidated portions of the lithosphere as well as on the morphological and mathematical relations of minerals and their chemical molecular arrangement, and the conditions of fossilization with reference to the changes in the solid parts of organisms.

The author is greatly indebted to Dr. Frank Wigglesworth Clarke's "Data of Geochemistry," and to Alfred H. Brooks's presidential address before the Geological Society of Washington, December 13, 1911, for the thoughts here presented.

*Gas and Oil Wells near Oberlin, Ohio:* GEORGE D. HUBBARD.

Exploitation of the Clinton sands of the Clinton formation northward from the Bremen field to Lorain County has gone far enough to find several good wells in the vicinity of Oberlin. Mostly gas of good quality; some yield oil too. Gas is found at a depth of about 2,170 feet below

surface which is at about 750 feet. Section contains much water in the limestones, also several feet of salt. Anticlinal theory does not seem to apply; gas is apparently in pockets or lenses of the sand in the calcareous shales. These sand beds are not continuous. Rock pressure varies in different wells from 600 to 950 pounds, and flow from 1,000,000 to 5,000,000 cubic feet per day.

*The History of the Bajadas of the Tucson Bolson of Arizona:* S. S. VISHNER.

The bajada is the long, gentle slope of detrital material at the foot of the mountains in bolsons or areas of centripetal drainage. The bajadas near Tucson have a length of about 10 miles and an average slope of  $2^\circ$  or 100 feet per mile. In spite of a difference of  $8^\circ$  or more in slope between the lower four miles of the canyons and the upper four miles of the bajada, erosion is now taking place on all portions of these thick terrestrial deposits. The explanation for this widespread erosion has been sought by many. The higher portions would, as shown by Salisbury, be eroded as the highlands were lowered, but not the lower portions, nor are certain other features to be thus explained. Over-grazing does not appear to be a sufficient cause. Davis concludes that in maturity the adjustment between one bolson and an adjacent lower one may result in the terracing in the higher. Changes of climate have been advocated: Barrell considers that bajadas were formed during the various glacial epochs and have since been destroyed; Huntington believes bajadas were formed in the interglacial epochs, of material which accumulated in the mountains during the glacial epochs. The present terracing he correlates with a recent increase of precipitation. The latter apparently opposing theories for bajada formation are in this region seemingly both essentially correct—Barrell's of the bajadas surrounding the lower, barren, warmer ranges, and Huntington's those of the higher, forested, cooler mountains upon which glacial conditions were approached since the bajadas of the former are more gentle, have a smaller percentage of clay and are more extensively eroded than those of the larger ranges. The frequency of freezing temperatures are believed to be important. At Tucson a decrease of  $10^\circ$  F. would increase the frequency about 200 per cent. and a  $20^\circ$  decrease would result directly in frost about 250 nights in the year. A different distribution of the precipitation would greatly effect the vegetal covering. The percentages of clay and boulder formation would fluctuate ac-

cordingly as would also accumulation and transportation. The Tucson bajadas appear to have been mainly formed at a time when the average temperatures were  $10^\circ$  or more lower; when the precipitation was greater and more uniform—either chiefly late in the glacial epochs (smaller ranges) or at their close (larger ranges). The present terracing is perhaps due to an increase in temperature and a different distribution and amount of rainfall abetted by the advancement of the area in the geographic cycle.

*The Relation of the Lime Creek Shales to the Cedar Valley Limestones of Floyd County, Iowa:* A. O. THOMAS.

The Devonian system of Iowa is represented by sediments belonging to two series, the Middle and the Upper Devonian. The stages of the Upper Devonian do not overlie each other, but each is locally developed and geographically separate. Moreover, each lies unconformably on the Cedar Valley stage of the Middle Devonian. Field study in Floyd County on the areal distribution and geological relations of the Lime Creek stage of the Upper Devonian has demonstrated a widespread unconformity at its base. A new substage, for which the name Nora limestone is proposed, is added as the lowest member of the Lime Creek stage.

*A Four Mile Section along the Missouri River South of Columbia, Missouri:* E. B. BRANSON.

Strata are well exposed along the bluff of the Missouri River and are, in general, nearly horizontal. Eight distinct and well-exposed unconformities occur within four miles.

*The Relation of Geological Activity to Conservation of Soil and the Waters of Flowing Streams:* LUELLA AGNES OWEN.

A view of the advance of geology as a science, and of early geological research, shows the growing appreciation of the all-important power of water in the development and progress of continents as well as their destruction or partial denudation for continual rebuilding. All atmospheric forces unite their energy with that of the flowing streams in every land to work without rest in tearing down the high places of the earth and transporting the waste for renewal of valleys and building new coast lines. So, the present geological epoch is preeminently the Age of Rivers, and in necessary works of conservation man may change the application of natural law to meet his needs and pleasure, but the law itself is unchangeable.

*Rock Classifications in Three Dimensions:* ALEXANDER N. WINCHELL.

Believing that tabular classifications are desirable because of their simplicity, but that, as previously devised, they are unnecessarily limited in their presentation of mutual relationships, a new classification of igneous rocks is presented which is in tabular form in three dimensions. It is based largely upon the principles and work of Rosenbusch, but it differs from his usage in various important respects, so that responsibility for it must lie with the author.

Secretary Section E

## SOCIETIES AND ACADEMIES

### THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and sixty-second regular meeting of the society was held at Columbia University on Saturday, February 22, extending through the usual morning and afternoon sessions. The attendance included thirty-eight members. Ex-president H. S. White occupied the chair, being relieved by Professors E. W. Brown and Frank Morley. Sixteen new members were admitted: Professor E. P. Adams, Princeton University; Dr. H. L. Agard, Williams College; Professor Fiske Allen, Kansas State Normal School; M. Farid Boulad, Egyptian State Railways; Professor J. A. Caparo, Notre Dame University; Mr. C. H. Clevenger, Kansas State Agricultural College; Dr. A. L. Daniels, Jr., Yale University; Mr. W. Van N. Garretson, University of Michigan; Mr. G. M. Green, Columbia University; Mr. C. E. Love, University of Michigan; Dr. Thomas Muir, Education Office, Capetown, S. A.; Mr. J. A. Nyberg, University of Wisconsin; Dean Marion Reilly, Bryn Mawr College; Professor B. L. Remick, Kansas State Agricultural College; Professor W. V. Skiles, Georgia School of Technology; Mr. J. N. Vedder, University of Illinois. Five applications for membership were received.

The society is about to publish the lectures delivered at the Princeton colloquium in 1909 by Professors G. A. Bliss and Edward Kasner.

The following papers were read at this meeting: Harris Hancock: "A theorem in the analytic geometry of numbers."

B. H. Camp: "The expression of a multiple integral as a simple integral."

G. M. Green: "Projective differential geometry of triple systems of surfaces."

C. A. Fischer: "A generalization of Volterra's derivative of a function of a curve."

L. B. Robinson: "Notes on the theory of systems of partial differential equations."

Oswald Veblen and J. W. Alexander, II.: "Manifolds of  $n$  dimensions."

R. G. D. Richardson: "Oscillation theorems for linear homogeneous self-adjoint partial differential equations with one parameter."

L. P. Copeland: "Concerning the theory of invariants of plane  $n$ -lines."

T. H. Gronwall: "On the summability of Fourier's series."

T. H. Gronwall: "On Lebesgue's constants in the theory of Fourier's series."

T. H. Gronwall: "On the degree of convergence of Laplace's series."

N. J. Lennes: "Note on Lebesgue and Pierpont integrals."

N. J. Lennes: "Finite sets and the foundations of arithmetic."

H. Bateman: "The expression of the equation of the general quartic curve in the form  $A/xx' + B/yy' + C/zz' = 0$ ."

H. Bateman: "Sonin's polynomials and their relation to other functions."

Dunham Jackson: "On the accuracy of trigonometric interpolation."

C. E. Wilder: "On the degree of approximation to discontinuous functions by trigonometric sums."

Edward Kasner: "Systems of curves connected with equiangular transformations."

The next regular meeting of the society will be held at Columbia University on Saturday, April 26. The Chicago Section will meet at the University of Chicago on Friday and Saturday, March 21-22. The San Francisco Section meets at Stanford University on Saturday, April 12.

F. N. Cole,  
Secretary

### THE ACADEMY OF SCIENCE OF ST. LOUIS

At a recent meeting of the academy held on February 17, 1913, Professor Nipher presented an abstract of a paper soon to be published by the academy, entitled "A Local Magnetic Storm."

The phenomena were produced by means of two steel magnets, placed on opposite sides of a magnetic needle, as in the Gaussian method of deflection. The needle was completely enclosed in a copper cylinder. Its motion was observed through a small glass window, covered with wire gauze, by

means of a telescope and scale. The needle was in the magnetic meridian, the two deflecting magnets being balanced against each other. The needle was also loaded with a few copper wires, and the earth's field was partially compensated, so that the period of oscillation of the needle was about twenty seconds. When one of the deflecting magnets is then connected with either terminal of an influence machine, the other terminal being grounded, its deflecting effect on the needle was increased. This effect was found to be varied by disturbances of the air in the room due to the movement of an assistant. The observed effect was not appreciably modified by wrapping the magnet in tinfoil. A puff of tobacco smoke over the deflecting magnet also changed the apparent deflecting effect. It gradually became apparent that a change in the permeability of the air was produced, when the magnet was put into contact with the influence machine in an adjoining room. Apparently, the electrified molecules of air arranged themselves along the lines of the magnetic field, with the planes of rotation of the electrical whirls within the molecules set at right angles to the magnetic lines. The permeability of the air was thus increased, in somewhat the same way that iron filings in the field of the magnet would increase it.

When the electrified air around the magnet is disturbed by a palm-leaf fan, the permeability of the air is decreased. By proper timing of these disturbing effects of the fan, the amplitude of swing of the needle may be gradually increased to four degrees of arc. By operating the fan during the other semi-vibration of the needle it may be brought quickly to rest.

Professor Nipher is now seeking to obtain photographs of auroral displays around the poles of a steel magnet.

*Corresponding Secretary*

#### THE BOTANICAL SOCIETY OF WASHINGTON

THE eighty-sixth regular meeting of the Botanical Society was held at the Cosmos Club, Tuesday evening, February 4, 1913.

The following persons were elected to membership: Professor R. Kent Beattie, Dr. Charles Brooks, Mr. J. G. Grossenbacher, Dr. Neil E. Stevens.

The following program was presented:

MR. T. H. KEARNEY: *Indicator Value of Natural Vegetation in the Tooele Valley, Utah.*

This paper outlined the results of an investigation conducted last summer by the Offices of Alkali and Drought Resistant Plant Investigations and of Biophysical Investigations of the Bureau of Plant Industry. The Tooele Valley lies between the Oquirrh and Stansbury ranges and extends to the south shore of Great Salt Lake.

It was found that the valley is occupied by some half dozen principal plant associations, each of which is characterized by the presence of one, or, at most, two dominant species of shrubs or perennial herbs. The presence of one or another association was found to be closely indicative of the moisture relations and salt content of the substratum. The areas occupied by the different associations are often so sharply defined as to be recognizable at a distance of several miles.

The presence of a good stand and growth of sage brush (*Artemisia tridentata*) is always associated with a soil of rather light texture, very dry during the summer months, free from alkali salts and with a low water table. This *Artemisia* association occupies mainly the higher lands of the valley. Descending the valley toward the shore of Great Salt Lake, successive zones are traversed which are occupied by the following associations: (2) *Kochia vestita*, (3) *Atriplex confertifolia* (Shadscale), (4) *Atriplex confertifolia* and *Sarcobatus vermiculatus* (Greasewood), (5) *Allenrolfea occidentalis*, (6) *Distichlis spicata* (Salt Grass) and two species of *Salicornia*.

Where associations 2 and 3 occur the soil is very dry during the summer, but has a higher moisture capacity than in the *Artemisia* association and the subsoil is strongly saline. Under association 4 the soil becomes saline to the surface and the ground water table is relatively high. Associations 5 and 6 occupy the wet and highly saline soils near the level of the water surface of the lake and are interrupted by bare expanses covered with a crust of salts (chiefly sodium chloride).

The suitability for crop production of the different types of land in this valley can be predicted with much confidence from the character of the native growth.

MR. HARRY B. SHAW: *The Control of Seed Production in Beets.*

Practically all sugar-beet seed used in the United States is imported. Successful attempts have been made in Utah, Idaho and Washington to produce sugar-beet seed, but in other regions

such attempts have not been very successful, inasmuch as many of the plants have failed to mature seed. Observations were made to ascertain the cause of this. In order to make the subject readily comprehensible attention was invited to the surprising responsiveness of the beet to environment; the responses may be grouped as follows:

1. The wild beet, a winter annual, ripening and dropping its seed early in autumn. The seed germinates before winter sets in, consequently the young seedlings are for many weeks exposed to a comparatively low mean temperature. In early spring—coincident with rising temperatures—the seed stem is put forth, the paucity of foliage being conspicuous.

2. The wild annual brought into cultivation soon assumes the biennial habit; its growth being in every known way stimulated from the sowing of seed onwards; planting is carefully planned so that the young seedling shall escape protracted periods of low temperature. In response, the roots become storehouses and fail to develop reproductive parts.

3. The cultivated beet, a biennial, not alone through selection, but more especially because its environments are entirely changed; it is withheld from those periods of restrained growth seen to operate upon the wild beet in its native habitat; instead, its growth is stimulated.

4. The cultivated beet reverts to the annual habit, whenever it is exposed in the seedling stage to conditions more or less identical with those of the wild beet at the same stage of growth.

5. Even when the beet is planted out the second spring for the production of seed, there are occasions and localities which cause in those beets a greater or less tendency toward non-seeding, ranging from almost normal seed production to absolute foliage conditions.

6. When placed under conditions where growth stimulus is great and constant, as in a well-heated greenhouse, the cultivated beet becomes perennial in habit, producing, year after year, nothing but foliage.

Mr. Shaw sought in these varied manifestations a common factor, or group of factors, which acting at a critical period in the life of the plant, might be found to control the manner of its development. Experiments were carried on in Utah during 1912 to determine, if possible, the nature of the conditions responsible for the variations mentioned.

It was discovered that the condition absolutely necessary for the perfect development of the reproductive parts is a period of restrained growth in the bud rudiments of seedlings, or the buds in the crown of so-called mother beets. While in general this condition is brought about by low temperatures (a mean temperature of 38 to 45° F. apparently being required for the sugar beet) when prevailing for several weeks, the necessary degree of growth inhibition may be brought about by other factors, such as pathological conditions, drouth, starvation. The withdrawal of such a period of inhibited metabolism, according to degree, will result in the greater or less degree of approach to foliage conditions, as opposed to the development of reproductive parts.

Thus, by a study of climatic conditions, suitable locations where the production of seed may be assured, can be selected with a considerable degree of certainty. The proper time to plant the mother-beets can also be indicated, so that we may be reasonably certain that the beets will produce seed.

This necessity for a period of inhibited metabolism, and the fact that it may be brought about by the conditions mentioned, may explain the remarkable inflorescence of moribund fruit trees, or of trees that have been carried, also the abnormal behavior of plants carried from a cool to a warm climate.

C. L. SHEAR,  
*Corresponding Secretary*

#### PHILOSOPHICAL SOCIETY, UNIVERSITY OF VIRGINIA MATHEMATICAL AND SCIENTIFIC SECTION

The fifth meeting of the session of 1912-13 of the Mathematical and Scientific Section was held February 17.

Professor W. H. Echols read a paper entitled "The Evolutionary Construction of the Imaginary Power of a Number and Its Expression as the Exponential Function."

Professor Thomas L. Watson read a paper by himself and Professor Stephen Taber on "Magmatic Names Proposed in the Quantitative System of Classification for some New Rock Types in Virginia."

Professor Watson presented a second paper by himself and Mr. Justus H. Cline. The subject of this second paper was "Petrology of a Series of Igneous Dikes in Central Western Virginia."

## UNION OF SOUTH AFRICA

Department of Agriculture

Appointment of Assistant Entomologist

Applications are invited for the post of ASSISTANT ENTOMOLOGIST in the Department of Agriculture of the Union of South Africa.

Applicants for the post must have had a College education embracing entomology and allied natural science courses, and must be capable of undertaking investigations of insect problems. Practical experience in economic entomology will be a recommendation.

The salary attaching to the post commences at £350 per annum and rises, subject to satisfactory service, by annual increments of £20 to a maximum of £450, but in the case of a fully competent man the prospects of promotion to a higher grade are good. In certain districts a local allowance is payable in accordance with the Regulations of the Public Service.

The successful candidate will be required to serve on probation for a period of twelve months and will be expected to acquire a knowledge of the Dutch and English languages within a reasonable period.

Applications supported by certificates of birth, health, character, education, previous employment or professional qualifications, and languages will be received by the undersigned not later than April 30, 1913.

THE mission of an academy of science is a function of the age in which it flourishes. The ancient academies accomplished a work now performed by the universities. The Italian academies of the Renaissance, variously estimated at from 500 to 700 in number, represent different purposes almost as numerous as the institutions themselves. But in general they were literary and scientific clans; they belonged to a period when learning was the possession of the few, to a period when one might still take all science for his domain.

The modern academy is, as a rule, closely allied with the sovereign power of some state, whose interests are promoted by it, consciously and unconsciously, in a variety of ways. The service which it renders is sometimes political, sometimes literary, sometimes scientific, sometimes social. But, so far as I can see, they all have, in common, these two ends, namely, the encouragement of the individual and service to the community.

The triple purpose of the Illinois State Academy of Science is clearly stated in the second article of its constitution as being "the promotion of scientific research, the diffusion of scientific knowledge and of the scientific spirit, and the unification of the scientific interests of the state"; just how this object can best be secured is the interesting subject of an after-dinner discussion this evening.

I leave this problem, therefore, with the

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

<sup>1</sup> Presidential address, delivered before the Illinois Academy of Science, at Peoria, February 21, 1913.

single remark that the importance of cultivating individual initiative and of handing on to the community the best there is in the achievements of science is not likely to be overestimated.

Symonds<sup>2</sup> points out that Athens and Florence owed their wonderful intellectual, artistic and literary success mainly to the fact that they nourished the individuality of their citizens; while Sparta and Venice, comparatively barren of permanent results, illustrate the lack of such encouragement.

I now invite your attention to one of the earliest members of the venerable and thankworthy Academy of the Lyncei, a man who represents in the highest degree the individuality then cultivated in Tuscany, a man whose impress upon his students was so deep that shortly after his death they united to form one of the most productive and justly celebrated of all the Italian academies,<sup>3</sup> a man whose written works fill twenty splendid quarto volumes,<sup>4</sup> a man who in his efforts to put before the people the best science of his times, endured opposition, criticism, disgrace and social ostracism throughout most of his thinking life. I refer to Galileo. But I shall speak only of what he did in physics, because I believe this phase of his work is too little known.

What Galileo saw through telescopes of his own make, though not of his own invention, is so familiar that possibly a majority of intelligent men think of him mainly as an astronomer. The spots on the sun, the mountains on the moon, the

satellites of Jupiter, the phases of Venus, the "triple character" of Saturn, the solar rotation period, lunar libration and earthshine are some of the celestial phenomena associated with the name of Galileo. These and his brilliant defense of the Copernican system are responsible for the impression that his accomplishments are chiefly astronomical.

To another large group of men he stands mainly for liberty, intellectual, social and religious. These men classify him with Giordano Bruno and De Dominis and Campanella who also had some experience with the cardinals of the Inquisition. For them Galileo is the man who dared to differ with Aristotle, the man who brushed aside the mists of philosophy, the man who banished church traditions from his thinking while he calmly pursued his search after unity in the physical universe.<sup>5</sup> It is doubtless his splendid stand for spiritual freedom which leads Goethe<sup>6</sup> in his historical sketch of optics to say:

Even though he never seriously studied the subject of color, I must at least adorn my page with his name.

But there is still a third group of men to whom the great Italian appeals most strongly because he has given them a new method of working and thinking, a new viewpoint, a new *aperçu*. To put this contribution in its proper perspective is not an easy matter; we are too near it and too familiar with it. If, however, one considers the time interval between Archimedes and Kelvin he can not fail to notice a sharp discontinuity in the progress of physics occurring about the beginning of the sev-

enteenth century. Just how commerce and industry led up to, and prepared the way for, this step is the subject of a most interesting chapter by a member of this academy, Professor Mann.<sup>7</sup>

Without underestimating the contributions of Pappus or Tartaglia or Benedetti or Stevinus or Leonardo da Vinci, to mechanics; and without denying the important rôle of statics in architecture and in other structural work, one may, I believe, fairly say that the years which intervene between Archimedes and Galileo are practically barren of progress in physics.

It is true, indeed, that during this interval a large number of isolated physical facts had been discovered; indeed, there is scarcely a chapter in physics in which some advance of this type can not be mentioned; but, during all this while, nothing in the way of development is seen; individual discoveries remain isolated; they do not bear fruit; speculation and guessing were still employed where we use observation and measurement and computation. Leonardo da Vinci likens a scientific conquest to a military victory in which theory is the field marshal; experimental facts, the soldiers. The philosophers who preceded Galileo had, in the main, been trying to fight battles without soldiers. The only possible exceptions to this statement are Roger Bacon, Leonardo da Vinci, Stevinus and Gilbert. They had measured some mechanical quantities—a few of them—masses and stresses—such as could be obtained by means of a steel-yard and a measuring stick; but they were still in the domain of statics. Now from a geometrical, esthetic or even utilitarian standpoint it is difficult to imagine any finer subject than graphical statics; and yet when we regard the progress of physics,

statics is to dynamics somewhat as osteology is to physiology, a veritable valley of dry bones. The live part of mechanics is kinetics, the study of masses which are in motion, the consideration of bodies which are changing their velocities, currents of water, oscillating magnets, vibrating strings, rotating wheels, electric motors, heat engines, electromagnetic waves, and X-rays. These are the problems over which men lose sleep; these are the questions which compel the interest of the physicist; these are the subjects whose mastery confers power upon the engineer. The one confessed aim of physical science is, indeed, to describe the motion of bodies in the simplest possible manner. Indeed, it is only by the aid of this modern science of the energy of motion that any of the ancient mechanical doctrines—such as the atomic theory of Democritus—have acquired validity; it is this same science which has rendered the heliocentric theory of Copernicus not merely “a plausible view” but the one possible view.

We pass now to a more definite question, namely, what contribution did “our Academician” make to the solution of problems of this type, to the science which now goes by the name of physics? To answer briefly and baldly, he instituted the method and set into motion the machinery by which practically all these problems have been solved, in so far as they have been solved at all. But lest I give the false impression that Galileo was the ancestor of all the physical sciences, I hasten to a more detailed answer of the query, What did Galileo?

1. First, no greater mistake could be made than to suppose that Galileo was the first man to differ with Aristotle; the academy of Cosenza, having opposition to the peripatetic philosophy as its avowed purpose, was established at Naples about

<sup>7</sup> Mann, “Teaching of Physics,” pp. 107–110 (Macmillan, 1912).

the time when Galileo was born; but he was the first man to offer *experimental evidence* against the conclusions of Aristotle; and in so doing he established what we now call the experimental method. He was not handing on an opinion which some "dusty-minded professor" had inherited from an ancestor of the same type.

Only two methods of investigation were known to the ancients, the philosophical and the mathematical; to these Galileo added a third, the experimental. The philosophical method consisted in assuming certain general principles and trying to find in them an *a priori* explanation of the universe. Briefly described, the attempt was to stare nature out of countenance. Failure was inevitable, not for want of intellectual acumen, but because, as every one in this assembly knows, it sometimes requires a lifetime of effort to explain a single detail. Witness almost any chapter in Darwin's "Origin of Species." Details must be mastered before one can pass to general principles.

The mathematical method consisted only in applying geometry to certain well-known areas, volumes and angles, especially to those angles observed in the sky, but always with the idea of describing the known rather than of discovering the unknown: the mathematicians do not appear to have put any deliberate questions to nature; or as Rowland said:

A mathematical investigation always obeys the law of the conservation of knowledge: we never get out more from it than we put in. The knowledge may be changed in form, it may be clearer and more exactly stated; but the total amount of the knowledge of nature given out by the investigation is the same as we started with.

The experimental method, established mainly by Galileo, not only combines the observations of the philosophers with the measurements of the mathematicians, but

adds deliberate experiment with a distinct purpose to interrogate nature concerning some detail of her behavior. Generalizations based upon these details the experimenter reserves for a later date. The high regard in which Galileo held experimental facts is reflected in the following from a letter<sup>8</sup> to the Grand Duchess Christina, dated 1615. He says:

I would entreat these wise and prudent fathers to consider, diligently the difference between opinionative and demonstrative doctrines, to the end that they may assure themselves that it is not in the power of professors of demonstrative sciences to change their opinions at pleasure.

Or witness the following paragraph from the "Saggiatore" as illustrating the great weight which Galileo attached to experimental evidence. He says:

We examine witnesses in things which are doubtful, past, and not permanent, but not in things which are done in our presence.

If discussing a difficult problem were like carrying a weight, then since several horses will carry more sacks of corn than one alone, I would agree that many reasoners avail more than one; but discoursing is like coursing, and not like carrying; and one barb by himself will run faster than a thousand Friesland horses.

In all his thinking nothing is exempt from experiment. Astronomy even, in his hands, ceases to be a purely observational science; for when he wishes to discover whether the bright portions of the moon's surface are rough or smooth, he sets up two surfaces, one rough and one smooth; then illuminates them with Italian sunlight. Desiring to learn at what rate falling bodies gain speed, he devises a time-measuring machine, invents a method of "diluting gravity" and actually measures the rate at which speed is gained. His discussions begin and end with experiment—

<sup>8</sup>"Nat. Ed.," Vol. 5, p. 326. Translated in Fabie's "Galileo," p. 157.

<sup>9</sup>"Nat. Ed.," Vol. 6, p. 340. Translated in Fabie's "Galileo," p. 187.

a method so familiar to us that we forget how recent and powerful it is.

His two great dialogues—one dealing with astronomy, the other with mechanics—abound in experiments—most of them apt and clever. Leonardo da Vinci advocates experiment: Galileo uses experiment.

2. The second great achievement of Galileo was his seizure upon momentum as the fundamental quantity in the science of mechanics, and his demonstration that velocity is a factor in momentum. Galileo was by no means the first to study and discuss kinematical problems.

Benedetti (1530–1590), one of the many distinguished alumni of the University of Padua, had not only expressed dissatisfaction with the artificial distinction between “violent” and “natural” motions, but had gone farther and had paved the way for mechanics and the differential calculus by recognizing the fact of continuous variation in motion: Benedetti<sup>10</sup> had in particular studied oscillatory motion and had shown that such a motion is continuous even when the vibrating particle is at rest at the end of its path. He had, in fact, introduced the modern idea of continuous variation. But none of the predecessors of Galileo had, so far as I have been able to discover, pushed their study of moving bodies beyond the mere consideration of change of position. None of them had recognized the inertia of the moving body as a fundamental—perhaps the fundamental—fact of mechanics. Princes and paupers, for ages, had stumped their toes against bricks and stones: they were doubtless quite as familiar as we with the mere fact of inertia. But to Galileo it was a cardinal fact, because he was the first to see that the future history of a body depends upon its possession of inertia. To

<sup>10</sup> Lasswitz, “Atomistik,” Bd. 2, pp. 14–23, gives a good description of Benedetti’s work.

him the importance of a motion is, in general, measured by the inertia involved, or, as was then said—the weight involved. Hence he assigned to the product of the weight and velocity of a body the name “momentum,” which is merely the Latin word for importance; as a synonym he sometimes uses the word *impetus*, thus emphasizing the impetuosity of motion.

But Galileo never got beyond the point where he measured inertia by weight, as, indeed, engineers still do—all, at least, except electric engineers. The invention of the idea of mass was reserved for Newton. Even Huygens,<sup>11</sup> who first mastered the idea of centrifugal force, never got beyond the point where he measured centrifugal forces in terms of weight, thus avoiding the conception of mass in all his work.

Those who wish to see just how clearly Galileo conceived that the future behavior of a body is connected with its inertia should read those propositions in his “*Mechanics*”<sup>12</sup> in which he calculates the path of a projectile by assuming that the horizontal speed of a shot, after it has left the muzzle of a gun, continues to be uniform. His repeated use of this principle makes it perfectly clear that he discovered what we now call—and perhaps properly call—Newton’s first law of motion. Galileo failed to generalize it by extending it to all bodies, whether subject to the earth’s gravitation or not. This Newton did because he had acquired the new concept of mass—that constant property which never deserts a body in any position or condition.

3. The next great step which Galileo

<sup>11</sup> Huygens, “*Horologium Oscillatorium*,” Part V., Prop. 13; or Hobart, “*School Science and Mathematics*,” Vol. 11, p. 692 (1911), for translation of Huygens’s paper.

<sup>12</sup> Galileo, “*Dialogues on Motion*,” Fourth Day, Problem I. et seq.

made was the discovery of the constant factor in the motion of falling bodies. One of his earliest experiments, performed while still a young man at the University of Pisa, was to allow a bronze ball to roll down a carefully prepared inclined plane, an experiment from which he cleverly inferred that while the position and speed of the ball were changing, the time-rate at which it gained momentum remained constant. It was with reference to these particular experiments that Goethe remarked "*dem Genie, ein Fall für tausend gelte.*" The experiment is completed by showing how one can compute the momentum (or speed) of a body after it has been falling for any given time or through any given distance. In all these computations, the unit of momentum employed is that which a body acquires in falling freely through an arbitrarily selected unit of distance.

As illustrating how tenaciously he clings to the idea of momentum, witness the following clear, exact and thoroughly modern definition dating from the year 1604:<sup>13</sup>

I call a motion uniformly accelerated when starting from rest its momentum, or degree of speed, increases directly as the time, measured from the beginning of the motion.

Observe that we have here, without any mention of the word, precisely the dynamical idea which we to-day use under the name of a "*constant force.*" There is, indeed, no necessity for the name; for Galileo attempts nothing more than to discover how the momentum of a body changes, owing to the presence of another body such as the earth in the neighborhood (action at a distance) or owing to contact with an elastic body such as the hot gases of exploding gunpowder in the barrel of a gun (action through a medium). Later generations had not yet beclouded the idea of force with "tendencies to motion"; they

had not yet identified it with that vastly more complex "muscular sensation"; they had not yet made it over in the form of a "man"; they had not yet named it an "agent"; they had not yet identified it with a state of stress or strain which one elastic body exhibits when held permanently at rest by another elastic body; still less had there been any attempt to convince people—principally high-school lads and college students—that all these various things are one and the same, since, forsooth, at various times we call them by one name, "force." Some of Galileo's most worthy successors, such as Clifford,<sup>14</sup> Poincaré<sup>15</sup> and Hertz, have pointed out our inconsistent definitions of force, and have advocated in the most outspoken manner, a return to the simple methods of this Italian academician.

The best known of all his experiments is, of course, that in which he proves that the time of fall is independent of weight, an experiment which completes to a first approximation the laws of falling bodies practically as we have them to-day. He accomplishes a second approximation by eliminating the buoyant force of the medium. He is prevented from making a third approximation only because he meets the barrier of viscosity, a barrier which still renders impossible the solution of any but a few simple cases in fluid motion.

The one remaining fundamental phenomenon of falling bodies is that the acceleration of gravity is independent of the substance of which the falling body is composed. This Galileo<sup>16</sup> proved by swinging, side by side, two pendulums, having bobs

<sup>13</sup> Clifford, *Nature*, Vol. 22, p. 122 (1880).

<sup>14</sup> Poincaré, lecture before the Wissenschaftlich Verein in Berlin, p. 116 (Teubner, 1912).

<sup>15</sup> "Nat. Ed.," Vol. 8, pp. 128-130, First Day, translated into German by von Oettinger, Ostwal's *Wiss. Klassiker*, No. 11, p. 76

<sup>16</sup> "Nat. Ed.," Vol. II, p. 166.

of lead and cork, respectively. When the suspension fibers had equal lengths and the pendulums swung through equal amplitudes, they had equal velocities at each point of their path. It is difficult to find, in Newton's hollow pendulum experiment, much more than a second approximation in which he eliminates the air resistance from this experiment of Galileo.

4. The fourth advance which we owe to Galileo is the observation that the momentum communicated to a body in one direction does not alter its momentum in a direction at right angles. This independence of components of momenta, now known as Newton's second law of motion, was in the hands of Galileo no mere philosophical theorem, no vague guess, but a practical rule of action to be employed in mechanical operations. It is by compounding a uniform horizontal velocity with an accelerated vertical velocity that he proves, for the first time, that the path of a projectile is a parabola. It was by means of this principle that he prepared a range-table for gunners. The fact is then that Galileo discovered and employed the first two of Newton's laws essentially as we use them to-day.

It requires more than sheer strength to climb a difficult mountain peak; one must start in on the right trail. More than mere intellectual ability is needed to make an important discovery in physical science; one must start in with the correct viewpoint. This viewpoint is precisely what Aristotle lacked and exactly what Galileo possessed. It is Gomperz,<sup>17</sup> the distinguished historian of Greek thought, who says:

The physical doctrines of Aristotle are a disappointing chapter in the history of science. They

<sup>17</sup> "Greek Thinkers," Vol. 4, p. 108, Berry's translation.

display to us an eminent mind wrestling with problems to which it is in no wise equal.

5. As a minor achievement of Galileo allow me to mention some discoveries to which he blazed a part of the road.

In a letter to a friend he says he had spent more years in the study of philosophy than weeks in mathematics. It is, therefore, extraordinarily surprising to find set forth in his "Dialogues on Motion"<sup>18</sup> all the detailed facts and ideas which are involved in the modern definition of an infinite quantity developed by Boltzmann, Cantor, and Dedekind, viz., an assemblage containing a part which may be put into one-to-one correspondence with the whole.

Again he paves the way, in a very distinct manner, for the differential calculus, in pointing out that the definitions<sup>19</sup> of constant velocity and constant acceleration hold only when the times considered are "all whatsoever." If, therefore, one wishes to employ these definitions in the discussion of variable motion he must take his time intervals indefinitely small.

The invention of the well-known thermoscope which Galileo employed in his lectures at Padua also belongs here; for while it is not a true thermometer it doubtless led immediately to those exquisite sealed instruments shortly afterwards constructed by the Accademia del Cimento and still preserved in the Tribuna di Galileo at Florence. The theory of "dimensions," first stated by Fourier, was led up to in the First Day of the Dialogues on Motion.

The principle employed in his measurement of the density of air<sup>20</sup> is one which is not only faultless in principle, but one which makes it plainly evident that Galileo had properly conceived that idea of atmospheric pressure which, in the hands

<sup>18</sup> First Day, "Nat. Ed.," Vol. 8, p. 78.

<sup>19</sup> Third Day, "Nat. Ed.," Vol. 8, p. 191.

<sup>20</sup> "Nat. Ed.," Vol. 8, p. 124, First Day.

of two of his students, led to the invention of the barometer, and, in the hands of von Guericke, to the air pump. Torricelli knew well the Dialogues on Motion.

6. Finally, Galileo was an inspiring teacher and built up at Padua a great school of physics. Many of his students lodged under his own roof; helped him in his own garden; ate at his own table. He had his own workshop and employed his own mechanicians. Generous with his time, his energy and his money, master of a fine literary style, endowed with a keen sense of humor, familiar with the best that had been said and thought in the world, standing in the front rank of investigators, is it any wonder that young men of talent hastened to Padua from all parts of Europe? Could any higher compliment be paid to a teacher than the devotion exhibited by the youthful Viviani, a lad in his teens, for his master already some seventy years old and a "Prisoner in Accetri"? If deferred payments of the kind that teachers mostly depend upon ever get as far as the next world, surely this courageous spirit, harried throughout his long life by poverty, ill-health and the censorship of the church, must have been gratified by the work of the Accademia del Cimento which was, with the exception of a single man, composed entirely of his students. Mechanics was the one subject to which he was devoted consistently and persistently throughout his life; it was the subject of his earliest investigation when a young man at Pisa; the subject upon which he lectured when in his prime at Padua; the subject of his latest and most mature reflection at Accetri. His most important contribution to dynamics was published in the seventy-third year of his age.

If, in conclusion, I were asked to summarize in a single sentence the principal contributions of Galileo to the science of

physics, I should mention the two following facts: (1) That knowledge of physical phenomena which is to receive "impersonal verification" and become useful, must be obtained mainly by experiment adapted to ask of nature some particular question. (2) That momentum considered as a function of time and position is a fundamental dynamical concept; or, in other words, to discover how the change of momentum of any body is connected with the physical circumstances in which the body is placed, is the one great problem of dynamics.

But perhaps, after all, his most important contributions lie outside of physics. Indeed Galileo has not yet shot his last arrow. For his life still teaches us that nothing is so because any man says it is so. His example still shows how experiment can rob a man of all arrogance of opinion, how familiarity with unsolved problems can give a man genuine humility, and how, on the other hand, the possession of clear experimental evidence arms him with sure confidence.

Critics tell us that Florence, during the Renaissance, shone with a borrowed light—a light reflected from Athens. But I venture to think that those who will take the pains to look over the pages of Galileo will find them self-luminous.

HENRY CREW

NORTHWESTERN UNIVERSITY

---

#### FACTS AND FICTION ABOUT CROPS

THE Association of Official Agricultural Chemists of the United States at the Norfolk meeting, in 1907, unanimously adopted a committee report<sup>1</sup> endorsing the following declaration:

It is as truly the duty of science to protect agriculture from error as it is to afford new truth.

<sup>1</sup> See Circular No. 123 of the University of Illinois Agricultural Experiment Station.

If "the farm is the basis of all industry," as was recently stated by James J. Hill, then science should not fail in this duty; for American agriculture is approaching a crisis, and the use of science must be depended upon to provide adequate support for our rapidly increasing population.

Already the question of food has begun to exert dangerous pressure in the United States, but so much of error and deception has been promulgated that even those who are to occupy the places of highest authority and influence are likely to be led into false positions whose foundations can only crumble beneath their feet.

There is no fiction in the starving poverty of our race in India, nor in the frequent famines of Russia, nor in the history of the dark ages following the ancient civilization of our people in the Mediterranean countries; and neither should the plans for the future prosperity of the Aryan in America be based upon fiction.

#### EXAGGERATED CROP REPORTS

Careful investigation reveals the fact that the reports from the federal bureau of statistics, as published by the secretary of agriculture, are highly exaggerated and deserving of the strongest condemnation, although all would be glad to give praise if these glowing reports were true; and, if the progeny of ninety-two million people and added millions of immigrants could live upon blind optimism or mere boasting, then duty would not compel this contribution toward the protection of truth and prosperity, by exposing error.

The following quotations are taken from the annual reports of the secretary of agriculture:

*From 1905 Report.*—Another year of unsurpassed prosperity to the farmers of this country has been added to the most remarkable series of similar years that has come to the farmers of any country in the annals of the world's agriculture. Production has been unequaled; its value has reached the highest figure yet attained.

*From 1906 Report.*—Economic revolution in the art and science of agriculture, which became noticeable in this country half a dozen years ago, has continued during 1906, with tremendous effect

upon the nation's prosperity. Crops so large as to be beyond any rational comprehension have strained the freight-carrying ability of the railroads.

*From 1910 Report.*—Year after year it has been my privilege to record "another most prosperous year in agriculture." . . . Nothing short of omniscience can grasp the value of the farm products this year. At no time in the world's history has a country produced farm products within one year with a value reaching \$8,926,000,000, which is the value of the agricultural products of this country for 1910. This amount is larger than that of 1909 by \$305,000,000, an amount of increase over the preceding year which is small for the more recent years.

A notable feature of corn production this year is the growing importance of the south. This has been manifested in a small way in very recent years, but now the increased magnitude of the crop in that section, both absolute and relative to national production, forces itself upon the attention.

The demonstration work among southern farmers is rapidly increasing. Organized in 1904 for the purpose of fighting the boll-weevil in Texas, this work has now extended to all of the southern states. . . . From 1904 to 1909 there was an increase from 1 to 362 agents in the field. The number has now reached 450, and the demand for more is urgent. . . . In 1909 figures from a large number of demonstrators showed a comparative increase of from 50 to 400 per cent. in the average yield of standard crops, and the figures for 1910 indicate similar results.

*From 1911 Report.*—Owing to the prevalence of high prices there has developed a general impression that the agriculture of this country is unequal to the needs of the increasing population. An investigation of the facts with regard to this condition failed to establish any cause for alarm. On the contrary, it is evident that this country has been passing through phases of agriculture in which declines in production per acre are the result of exploiting new land and in which recuperation follows with a greater pace than that of increase of population.

The Department of Agriculture has had success in the south through object lessons in the field, where the best southern farmers in their counties were the instructors. This method should be organized in all the states.

*From 1912 Report.*—The record of sixteen years

has been written. It begins with a yearly farm production worth \$4,000,000,000 and ends with \$9,532,000,000. . . . During the past 16 years the farmer has steadily increased his wealth production year by year, with the exception of 1911. . . . Beginnings have been made in a production per acre increasing faster than the natural increase of population.

In the issue of February, 1913, of the *Crop Reporter*, "published by authority of the secretary of agriculture," occurs the following:

Statements have been made recently by some writers and lecturers, to the effect that the yield per acre of crops in the United States is diminishing from year to year. A study of crop yields indicates that there was such a tendency toward lower yields during the seventies and eighties, but during the last 20 years the tendency has been the reverse. . . . In order to show this trend graphically, eight charts are published in this issue of the *Crop Reporter* which show the yearly change and the average change of yield per acre of eight important crops. In these charts the downward tendency until about 1890, and since then the upward trend, is strikingly shown. The recent tendency toward enlarged production per acre is general throughout the United States.

By referring to the *Crop Reporter* for January, 1911, we find a similar statement:

That the final stage of better agriculture and

increased production has been reached in many states for a varying number of crops, and that production per acre is not only beginning to exceed the normal increase of population, but really to exceed the actual increase. . . .

The potentiality of agricultural production as a national achievement sufficient for growth of population has been so numerous and so thoroughly demonstrated as to be now beyond intelligent question. The Farmers' Cooperative Demonstration Work, now carried on in 12 cotton states, employs 375 traveling agents and has many thousands of demonstrating farms. It is proving by results on thousands of farms that preparation of the soil so as to make the best seed bed adds 100 per cent. to the average crop on similar lands with an average preparation in the old way; that the planting of the best seed makes a gain of 50 per cent.; and that shallow, frequent cultivation produces an increase of another 50 per cent., making a total gain of 200 per cent., or a crop three times the average crop.

It will be noted that all of this enormous increase is secured with no suggestion of soil enrichment, in strict harmony with the erroneous teachings<sup>2</sup> of the Department's Bureau of Soils:

<sup>2</sup> See Bureau of Soils Bulletin, No. 55, pp. 66, 79, 80; or SCIENCE, November 8, 1912, p. 621.

The soil is the one indestructible, immutable asset the nation possesses. It is the one resource that can not be exhausted; that can not be used up. . . . It is evident that it can not wear out, that so far as the mineral food is concerned it will continue automatically to supply adequate quantities of the mineral plant foods for crops. . . . As a national asset the soil is safe as a means of feeding mankind for untold ages to come.

#### CROP ESTIMATES MEASURED BY THE CENSUS

Fortunately, there is a trustworthy measure applied to the progress or retrogression of this country every ten years, when every farmer and land owner in all the states must make a sworn statement to the Bureau of Census in regard to his crops and herds; and, fortunately this statement is not subject to subsequent revision or inflation by any "estimates" of the "Crop Reporting Board" with an "optimistic" secretary of agriculture as the chairman.

Thus, while the "crop statistics" of the agricultural department claim an increase of 50 per cent. in the production of corn in the southern states from 1899 to 1909, the data from the U. S. Bureau of Census show an actual decrease of 7 per cent. In other words, the Department of Agriculture reports that the total production of corn for the thirteen states from Texas and Arkansas to the Atlantic, and south of the Ohio and Potomac, was increased by 239 million bushels from 1899 to 1909; while the figures from the Bureau of Census prove that instead of an increase there was a positive decrease of 31 million bushels.

The accompanying statistical data and graphic illustrations reveal the percentage of inflation or boasting by the agricultural department as compared with the census facts relating to corn production in the individual states.

#### STATISTICAL ILLUSTRATIONS

The census reveals an increase in the population of contiguous continental United States of 21 per cent. during the last decade (from 76 million to 92 million people). The Bureau of Census also found an increase of

4.8 per cent. in farm land, and increase of 15.4 per cent. in *farmed* land, which means the land used for the production of crops, including pasture for live stock.

But has our increased production per acre amounted to more than 21 per cent., as the above quotations would lead us to believe? If so, our total increase in production should be 39.6 per cent., considering that we are farming 15.4 per cent. more acres. But the report of the Bureau of Census shows only 1.7 per cent. increase in the total production of all cereal crops, including corn, wheat, oats, barley, rye, rice, buckwheat, Kafir corn, emmer and spelt, the aggregate production having been 4,439 million bushels in 1899 and 4,513 million bushels in 1909; and a comparison of the crop "statistics" of the Department of Agriculture for these years with the averages for the three-year periods, 1898 to 1900, and 1908 to 1910, respectively, shows that, on the whole, 1909 was a slightly more favorable season than was 1899, for the production of the cereal crops.

*An increase of 15.4 per cent. in farmed land with an increase of only 1.7 per cent. in production reveals the truth of reduced yield per acre.* And neither official "estimates" nor official boasting can controvert this established American fact.

#### SHORTAGE OF ANIMAL PRODUCTS

We might expect and hope that a much larger increase would be found in the live stock produced during the decade on the farms of the United States, but instead we find no increase at all. In fact, the number of cattle decreased by six million (from 68 to 62 million head); the swine decreased by five million (from 63 to 58 million head); and the sheep decreased by nine million (from 62 to 53 million head); while horses and mules increased by less than three million (from 22½ to 24 million on farms, and from 25 to 27½ million all told, including those in cities).

(The time of year the counts were taken varied by six weeks, June 1, for 1900, and April 15, for 1910, but even with possible allowances for this variation, the number of

cattle, sheep and swine plainly decreased during the decade.)

#### THE TRUTH ABOUT COTTON

The cotton crop showed a substantial increase of 11.7 per cent. in total production, and, furthermore, 1909 seems not to have been a favorable season for cotton; but, on the other hand, the acreage in cotton increased by 32 per cent. from 1899 to 1909; and the combined reports of the Department of Agriculture (on acreage) and of the Bureau of Census (on production) reveal the fact that the yield per acre of cotton was not only less in 1909 than in 1899, but the average yield per acre for the four years 1907, 1908, 1910 and 1911, was also less than the average for the four years 1897, 1898, 1900 and 1901. This notwithstanding the boasted influence of the hundreds of "best southern farmers in their counties," who accepted appointments on the Department's pay roll as "field agents"; and it is a question of exceeding importance whether the "farm demonstrators" of either the south or the north should be appointed by the secretary of agriculture. Should they not rather be appointed by the agricultural colleges of the respective states, in order that they may be selected because of their thorough training in the scientific principles which must constitute the foundation of truly permanent systems of agriculture, as well as for their knowledge and experience in the science and practise of agriculture in their own state, and be held directly responsible to their home people? There is the gravest danger that a federal appointee in every county will often exert more influence politically than agriculturally.

#### POTATOES INCREASE

The reports of the Bureau of Census show that the only important increase in crops of large significance for food is in potatoes, a crop that is grown to a considerable extent on the market gardens enriched by heavy applications of animal fertilizers from the city, produced, of course, at the expense of the farms which supply the cities with hay and grain.

#### DECREASE IN EXPORTATIONS

When we consider the facts revealed by the Bureau of Census, it is not strange that, in order to feed our increasing population, we were compelled to decrease our exportation of wheat for making bread, and of corn for making meat. As an average of the first four years of Secretary Wilson's administration (1897 to 1900), compared with the average for 1907 to 1910, our annual exportations decreased from 210 million to 108 million bushels of wheat, and from 196 million to only 49 million bushels of corn. (These are not estimates, but facts.) In percentage of total "estimated" production, the corn exports decreased from 10 per cent. to 2 per cent., and wheat exports decreased from 37 per cent. of our production for 1897 to 1900, to only 16 per cent. of the production for 1907 to 1910.

#### THE GREATEST DECEPTION

And yet, if we ignore the census facts, and accept only the "estimates" of the Department of Agriculture, a comparison of averages of the "statistics" for these two four-year periods would show that, after deducting the actual exportations, our average annual supply for domestic consumption increased during the decade from 359 million to 575 million bushels of wheat, and from 1,806 million to 2,741 million bushels of corn; or, in other figures, these four-year averages would show that our supply of wheat for bread increased during the decade by 60 per cent., and that our domestic supply of corn for the production of meat, etc., increased by 52 per cent.; whereas, our population increased by only 21 per cent. during the same decade.

Thus the only real basis for the common complaint of the people regarding the food supply is that they can not live on "statistical" fiction.

In his annual report for 1912, Secretary Wilson makes the following generous statement:

The great and growing movement carried on by the department for agricultural betterment has not been sustained solely by one man.

It must also be recognized that the faults

## SCIENTIFIC NOTES AND NEWS

It is announced that Dr. H. B. Fine, professor of mathematics in Princeton University, has been offered by President Wilson the ambassadorship to Germany.

DR. DAVID F. HOUSTON, secretary of agriculture, will retain the chancellorship of Washington University on leave of absence. Professor F. A. Hall, dean of the college, has been appointed acting chancellor.

PROFESSOR WILLIS LUTHER MOORE, who has been chief of the United States Weather Bureau since 1895, will retire from this office on July 31.

DR. ELIE METCHNIKOFF, assistant director of the Institute Pasteur, Paris, has declined the directorship of the Institute of Experimental Medicine at St. Petersburg, vacant by the death of Dr. B. Podvyssotsky.

The ministry of public instruction of the French government has selected Dr. Maxime Bôcher, professor of mathematics in Harvard University, as exchange professor for 1913-14. His term of service will fall in the winter semester and will be spent at the University of Paris.

PRESIDENT DAVID STARR JORDAN, of Stanford University, has leave of absence to go to Europe in the interest of the peace movement.

PROFESSOR ARTHUR SCHUSTER, F.R.S., has been elected president of the Physical Society, London.

PROFESSOR W. M. DAVIS, of Harvard University, has been elected honorary member of the Hungarian Geographical Society at Budapest, and foreign member of the Swedish Anthropological and Geographical Society at Stockholm.

ON March 1 there was given in New York City, at Delmonico's, a dinner to Professor Russell H. Chittenden, director of the Sheffield Scientific School of Yale University, by his former pupils and a few other friends. Nearly one hundred were present, there being representatives of almost every Yale class from 1874 to 1908. Dr. Frank S. Meara, '90, acted as toastmaster and addresses were given

by Dr. John A. Hartwell, '89 S., chairman of the committee having the dinner in charge; Professor Graham Lusk, '96 Hon.; Professor Henry H. Donaldson, '79; Professor W. T. Sedgwick, '77 S.; Professor Harvey Cushing, '91; Dr. Elliott P. Joslin, '90 and '91 S.; Dr. P. A. Levene, and Professor Chittenden. At the close of the speaking, Dr. Meara announced that the National Institute of Social Sciences had voted a medal to Professor Chittenden in recognition of the distinction he has attained in original investigation in the field of physiological chemistry. Dr. H. Hollbrook Curtis, '77 S., secretary of the institute, made the presentation. Professor Mendel then presented to Professor Chittenden a set of engrossed resolutions which had been adopted by his fellow members of the board of trustees of the Sheffield Scientific School. It was announced by the committee, through its chairman, that Professor Chittenden's pupils were desirous of expressing their appreciation of his work in some such way that it might have a permanent value, and that to this end there was being raised the Russell H. Chittenden Fund, the income from which should be expended for the benefit of the department of physiological chemistry in the Sheffield Scientific School.

ON March 25, 1914, Geh. Ober-Regierungsrat Professor Dr. A. Engler, professor of botany in the University of Berlin, director of the Royal Botanic Garden and Museum at Berlin-Dahlem, member of the Academy of Science of Berlin, will celebrate his seventieth birthday. In order to commemorate this occasion, his friends in Germany and throughout the world have issued a circular letter requesting that subscriptions toward a marble bust be sent to Professor Dr. Wittmack, Berlin, N. W. 40, Platz von dem neuen Tor 1. The bust will be made by Herrn Bildhauer Manthe, of Schmargendorf.

PROFESSOR RALPH HOAGLAND, head of the division of chemistry of the College of Agriculture, University of Minnesota, has resigned and gone to Washington, D. C., where he will enter on his work in the Bureau of Animal Husbandry.

H. B. HUMPHREY, formerly head of the department of botany in the State College of Washington, has been appointed to fill the position of pathologist in charge of cereal disease investigations in the Bureau of Plant Industry of the Department of Agriculture.

PROFESSOR E. O. JORDAN, of the department of pathology and bacteriology in the University of Chicago, has accepted an invitation to become a member of the national commission for the determination of a standard of purity for drinking water. This commission has been formed in connection with the enforcement of regulations relative to pure drinking water, and its object is to establish a federal standard which shall be generally applicable.

PROFESSOR GEORGE D. STRAYER, of Columbia University, has been appointed chairman of a committee of fifteen of the National Council of Education to report on standards and tests of educational efficiency.

DONALD F. MACDONALD, geologist of the Isthmian Canal Commission, left Panama on March 11 for a month or more of geological exploration in the interior of Panama. The work will be carried on under the auspices of the Smithsonian Institution.

MR. VILHJALMUR STEFANSSON lectured before the members of the Royal Geographical Society on March 10 on "The Arctic Islands and their Eskimo Inhabitants." Mr. Stefansson, as has been announced, is at the head of a scientific expedition which will start from Victoria, British Columbia, in June, to explore the Arctic shores of Canada and to make further studies of the Eskimos of Victoria Island on behalf of the Canadian government.

PROFESSOR CHARLES RICHMOND HENDERSON, head of the department of practical sociology in the University of Chicago, who has been the Barrows lecturer for six months in the chief cities of India, China and Japan, will resume his regular work at the university near the opening of the spring quarter. The Barrows lectureship, which was established by Mrs. Caroline E. Haskell, provides for a series of lectures in the orient every three years on

the general subject of the relations of Christianity to other religions.

ON March 8 Professor S. F. Acree, of Johns Hopkins University, lectured before the chemistry department of Princeton University on "The Reactions of Both the Ions and the Non-ionized Forms of Electrolytes."

ON March 12 Professor Hugo Münsterberg delivered a lecture at Johns Hopkins University on "Psychology of Labor."

MR. FRANK P. STOCKBRIDGE, editor of *Popular Mechanics*, will give a series of weekly lectures on journalism to the students of the course in journalism at the University of Wisconsin this spring.

A COURSE of four public lectures on the theory of the solid state, has been delivered at University College, London, by Professor W. Nernst, director of the Institute of Physical Chemistry in the University of Berlin.

A NUMBER of friends, colleagues and pupils of the late Paul Segond have planned a memorial fund in honor of the memory of the surgeon. The income will be used to help internes approved by the council of the Faculté de médecine at Paris to pursue research work and to prepare for their examinations.

It has been decided to perpetuate the memory of the late Alderman C. G. Beale, vice-chancellor of Birmingham University, by (1) the endowment or partial endowment of a chair in the university to be selected hereafter by the university council, and to be called the Beale chair; and (2) a collection of British birds and their nests, mounted in their natural surroundings, to be placed in cases in the first room of the future Birmingham Natural History Museum. Sir Charles Holcroft has promised a donation of £5,000, to be devoted to the endowment of the university chair and there are other gifts amounting to £4,000.

IN November last a meeting of old students and friends of the late Professor Tait was held in the physical laboratory of the University of Edinburgh, Principal Sir William Turner presiding, when a committee was appointed to establish a memorial. The com-

mittee has now decided to recommend the raising of a fund of from £20,000 to £25,000, for the purpose of endowing a second professorship of natural philosophy in the university. The proposed chair would be connected with the department of Professor Tait's work in which he achieved especially conspicuous success, namely, the application of mathematics to the solution of physical problems, including those which bear upon engineering and other departments of applied science; and the committee feel sure such a chair would not only form an appropriate and worthy memorial, but would also be in itself of the highest utility. The committee are making every effort to bring the project to the attention of all old students, both at home and abroad, and they are confident of getting into communication with over 6,000 of them. They feel justified, however, in appealing not to old students merely, but also to men who were associated with the professor in any department of his work; to natural philosophers, mathematicians and scientific men generally, who through their study of his publications have become indebted to him as a teacher; to those who are interested in the progress of the Scottish universities, and recognize the great value of his services to education; and to such of his fellow citizens as take pride in his scientific eminence and recall with interest his picturesque personality. The hon. secretary, Professor J. G. MacGregor, the University, Edinburgh, will be glad to furnish any information that may be desired, either by letter or, in cases in which it may be possible, by personal interview. Subscriptions should be sent to the honorary treasurer, Sir George M. Paul, 16 St. Andrew Square, Edinburgh.

A MEMORIAL to the late Sir J. D. Hooker, which has been placed in the parish church at Kew, near the similar memorial to his father, Sir W. J. Hooker, was unveiled by Lady Hooker on February 22. It consists of a mural tablet of colored marble bearing an inscription, below which is a Wedgwood medallion portrait of Sir Joseph, flanked and supported by five panels containing Wedgwood figures of plants with which there had grown up some especial association.

THE death is announced, at the age of ninety-one, of Major-General Henry Clerk, who was elected a fellow of the Royal Society so long ago as 1848. He was the author of papers on the strength of timber, and the flow of liquids through small orifices and other subjects.

DR. RUDOLPH FRANK, professor of surgery at Vienna, has died at the age of fifty years.

It is stated in *Nature* that Mr. R. J. Balston, of Maidstone, has presented to the British Museum (Natural History) his well-known collection of humming-birds. The birds are mounted and arranged in forty-nine cases, each of which contains a group of two or more species. The total number of specimens in the collection is stated in Mr. Balston's manuscript to be 3,315, representing 162 genera and 480 species. Of these, 2,674 are skins, and 199 nests, some of the latter containing eggs. As soon as arrangements are made for its reception the series will be placed on exhibition in one of the corridors on the first floor of the zoological department. This collection and the Gould collection will render the exhibited series of humming-birds one of the finest, if not actually the finest, in the world.

THE Peabody Museum of American Archeology and Ethnology of Harvard University, has recently received two important acquisitions. The first is a valuable collection of prehistoric pottery from the mounds of the Red River region, Arkansas. This pottery, which is the gift of Mr. Clarence B. Moore, '73, of Philadelphia, Pa., came to the museum in several hundred fragments. They have now been cemented together and added to the regular exhibit. The other acquisition is a large collection of stone implements from the Island of Grenado, W. I., the gift of Dr. Thomas Barbour, '06.

A WEEKLY journal entitled *Die Geisteswissenschaften* has been established under the editorship of Dr. Otto Buek, of Berlin, and of Professor Paul Herre, of Leipzig, published at Leipzig by Veit and Co. The scope of the journal includes philosophy, psychology, mathematics, religion, history, philology, art,

law, sociology and education. The announcement states that the journal undertakes "für das Gebiet der Geisteswissenschaften ein ähnliches Programm verwirklichen, wie ihm für die Naturwissenschaften in England die 'Nature,' in Amerika die 'Science,' in Deutschland 'Die Naturwissenschaften' nachstreben."

We learn from *Nature* that the will of the late Mr. Rowland Ward, the taxidermist, directs that the trustees with respect to his charitable bequests shall expend 500l. per annum out of the income of his residuary estate, after the legacies and annuities specified have been paid, for a period of ten years in the purchase of specimens to be presented to the Natural History Museum, South Kensington. The residue of his estate is left in equal shares to such eight of fourteen selected charitable and other institutions as his widow shall choose. In default of his widow's selection within twelve months of the testator's decease, the whole of the fourteen institutions—which include the Natural History Museum—are to share equally.

THE only public standardizing and testing laboratory for public utilities and industries generally, outside of the one maintained by the Bureau of Standards at Washington, has just been established by the regents of the University of Wisconsin, in cooperation with the Wisconsin Railroad Rate Commission. The purpose of the university's new laboratory is to render more direct service to public utilities and to industries of the state by supplying them at a reasonable cost with the opportunity to have meters and similar instruments scientifically tested. Hitherto the smaller public utilities and industries that could not afford to maintain testing laboratories of their own have been compelled to have their testing done as favors by a few large companies that could maintain testing laboratories.

The following lectures are being given at the University of Minnesota:

January 17—"Eugenics and Race Betterment," Dr. Victor C. Vaughan, dean of the department of medicine and surgery, University of Michigan.

January 28—"Cancer and its Prevention," Dr. L. B. Wilson, of the Mayo Hospitals, Rochester, Minnesota.

February 11—"Heredity and Environment," Dr. E. L. Tuohy of Duluth.

February 25—"The Nature of Disease," Dr. W. T. Councilman, professor of pathologic anatomy, Harvard Medical School.

March 11—"Public Health a Public Duty," Dr. Mazyck P. Ravenel, professor of bacteriology, University of Wisconsin, and director of the Wisconsin State Hygienic Laboratory.

April 1—"The People's Responsibility in Dealing with Public Health Problems," Dr. H. M. Bracken, executive officer, Minnesota State Board of Health.

April 15—"The Need for an Efficient National Health Service in the United States from an Economic Standpoint," Dr. John B. Murphy, professor of surgery, Northwestern University Medical School.

April 29—"The Profession of Medicine; an Agency in Social Service," Dr. Richard Olding Beard, professor of physiology, University of Minnesota.

May 6—"The Growth of Hygienic Ideals," Dr. Henry B. Favill, professor of medicine, Rush Medical College.

THE United States Bureau of Education has just published a *Bibliography of the Teaching of Mathematics*, covering the period from 1900 to 1912, by David Eugene Smith and Charles Goldziher. This bulletin gives 1,849 titles of books and articles on the teaching of mathematics that have appeared since 1900. The bulletin will be sent free upon application to the United States Commissioner of Education, Washington, D. C.

WE learn from the London *Times* that an arrangement has been made for cooperation between the British board of trade and the principal Atlantic steamship lines in carrying out during the present year the recommendations of the merchant shipping advisory committee in their report on life saving at sea with respect to stationing a vessel for ice observation to the north of the steamship routes across the North Atlantic. In accordance with the advice of a special conference summoned by the board of trade to consider the best means of giving effect to this recom-

mendation, it is proposed that a vessel should be stationed off the east coast of North America to the north of the steamship routes during the coming spring to watch the break-up of the ice and to report its movement on the way to the routes. The *Scotia*, a whaler, formerly employed in the Scottish Antarctic Expedition, has been chartered to carry out this work, and it is anticipated that she will be ready to leave Dundee, where she is at present lying, about the end of this month. The vessel is being fitted with a Marconi wireless installation having a long range, so that she will be able to keep in touch with the wireless stations in Newfoundland and Labrador. The cost of the expedition will be shared between his majesty's government and the principal Atlantic steamship lines. In order to make the necessary observations in connection with the movement of the ice, there will be three scientific observers in the *Scotia*. As the vessel will from time to time be stationary, it is expected that these observers will be able to make oceanographical and meteorological observations as to currents, etc., which will be of general scientific interest, as well as of direct value to the work in hand. The *Scotia* is a wooden barque of 357 tons, built at Drammen in 1872, and is fitted with an auxiliary steam engine.

EIGHT trains sent out to all parts of Wisconsin by the College of Agriculture of the University of Wisconsin to demonstrate better farming methods reached 32,275 people, according to the report of the men in charge of the trains. These trains traveled about the state for thirteen weeks stopping every little way to give farmers an opportunity to visit them, and learn how their crops and livestock could be improved. Men from the agricultural college accompanied each train and lectured wherever stops were made. The trains were of three kinds. One kind was devoted to livestock, another to grains, and the third to potatoes. In the livestock trains prize animals were shown together with exhibits illustrating the care and feed of them. Lectures and informal talks on the value of using

pure-bred animals and kindred subjects, supplemented the various exhibits. Exhibits illustrating the good results attending the use of high-grade seed grains, how to improve the quality and yield of potatoes, etc., were shown in the grain and potato demonstration trains.

WITH Admirals Bradford and Chester in attendance, Captain J. L. Jayne, superintendent of the U. S. Naval Observatory, inaugurated Monday afternoon, February 10, a system of fortnightly meetings of the scientific staff for the discussion of topics relating to the work of the observatory. Professors Skinner and Frisby, now retired, but formerly for many years actively engaged in the work of the observatory, also took part in the proceedings. The paper of the afternoon, by Dr. W. D. Horigan, librarian, on "The Founding of the Observatory," detailed the meager progress of astronomy in this country during the eighteenth and the early part of the nineteenth centuries, and traced the efforts of various learned men and statesmen to establish a national astronomical observatory, up to the crowning of their efforts in the founding of the U. S. Naval Observatory in 1842. For the bringing about of this event the scientific world is directly indebted to Lieutenant J. M. Gilliss, U. S. Navy. In the discussion following the paper, Admiral Chester, formerly head of the observatory, stated that the paper should be printed in order that astronomers the country over should benefit by the thorough researches of the author.

ACCORDING to the *Journal* of the American Medical Association the American Telephone and Telegraph Company, the Western Union Telegraph Company and the Western Electric Company have made public a comprehensive plan for the payment of sick benefits and life insurance for their 175,000 employees. It is said that \$10,000,000 is available for this purpose. In connection with this pension plan there is to be gradually established a system of medical supervision and preventive sanitation designed to preserve the health of employees. The preventive measures will not only include early detection of disease among

employees, but also a supervision of sanitary conditions in offices and workshops and the instruction of employees in hygiene. The plan does not necessarily propose to furnish medical attendance to employees, but it will aid them in securing prompt and efficient treatment. Arrangements will be made with hospitals throughout the country for the prompt reception of those who seek this kind of treatment. It is believed by the companies that this plan will be an economical advantage to both parties. Dr. Alvah H. Doty, formerly health officer of the port of New York, has been appointed director of this department.

With a view of elucidating the history of native cotton, Mr. Frederick L. Lewton, of the U. S. National Museum, has written a pamphlet entitled "The Cotton of the Hopi Indians: A New Species of *Gossypium*," forming publication No. 2,146 of the Smithsonian Miscellaneous Collections. The fact that cotton was used and of necessity cultivated by the Indians, is recorded by several early Spanish explorers, as it has been more recently by many ethnologists. In the villages of the cliff-dwellers of Mesa Verde National Park numerous fragments of cotton cloth have been unearthed, and, in Utah, the seeds of the plant itself have been found. To-day, among the Hopi Indians of Arizona, the cotton plant is highly esteemed, and its fiber enters into many of their ceremonies, as well as into many practical household activities. It is considered essential by them that all strings employed in religious services be of native cotton. These strings of cotton are used to bind together prayer sticks and offerings of all kinds, and are placed in the trails entering the pueblos where ceremonial services are in progress; the badges of the chiefs are all wrapped with native rough-spun cotton strings; and cotton is also used to weave ceremonial kilts, belts and wedding blankets. Unfortunately the native Hopis, once deft in the art of weaving blankets, mantles, rugs and other articles from cotton, now find it far easier to purchase either the yarn already spun, the cloth already woven, or the complete

garment, and thus the art is gradually being lost. Cotton is still cultivated by them, however, to a small extent, in a village in the western Navajo Reservation and in another of the Moqui. The Department of Agriculture has carried on experiments with Hopi cotton for the past seven years. This particular species of cotton is remarkable in the rapidity with which it grows and the early date at which it blooms, it being the earliest to blossom of several hundred species put to test. Plants of this species have borne ripened bolls in eighty-four days from the sowing of the seed. Following a pertinent discussion as to the history and development of this particular sort of cotton, Mr. Lewton describes botanically the distinguishing features of a new species which he calls *Gossypium hopi*, and which is illustrated by five plates showing the growing plants, the flowers and the maturing and ripe bolls.

How the county "poor" farms of Wisconsin are being utilized to convince farmers of the advantages of up-to-date methods of agriculture, is explained by F. B. Morrison, assistant to Dean H. L. Russell, of the University of Wisconsin College of Agriculture, in the current number of the university's alumni magazine. In 1909 the college of agriculture instituted field demonstrations on several "poor" farms. The most approved methods of agriculture are put into practise on these fields so that the farmers of the surrounding country can see for themselves the results of simple improvements over their own methods. Each county farm is also made the center for distribution of pure-bred seed grain, bred scientifically at the college of agriculture. The demonstration fields are located on main traveled roads so that farmers passing by may see the results during the entire growing season. Farmers are always welcome at the demonstration fields and are encouraged to ask as many questions as possible. When the demonstration crops are at their best an annual demonstration picnic is held to which all the surrounding farmers and their families are invited. Sometime during the day of the

picnic all the participants are taken out to the demonstration fields and there the methods used to secure high yields are explained by professors from the agricultural college. How popular these meetings are is shown by their growth in attendance. In 1909 the average number present at a meeting was 80; this year it was 450. A notable result of these demonstration fields and demonstration picnics is the great improvement in agricultural methods in the sections where they are in force.

---

#### UNIVERSITY AND EDUCATIONAL NEWS

THE London correspondent of the *Journal* of the American Medical Association writes that the British government has made arrangements for taking part in the tropical diseases exhibition to be held at Ghent this year. The London School of Tropical Medicine, the Liverpool School of Tropical Medicine, the Cairo and Khartum schools, the navy and the army will be represented. Each of these organizations has been given certain diseases to illustrate in a popular manner, so that people may realize what is being done to make the tropics habitable to mankind. The cases will contain specimens of the insect pests which are the cause of the spread of disease in the tropics, with examples of the culture of bacteria taken from their blood, and numerous microscopic and photographic views of the development of the different stages. In all, thirteen diseases will be illustrated. The London School of Tropical Medicine will make a complete display of the work in progress in connection with cholera, beriberi and elephantiasis, including any fresh information available consequent on the outbreak of cholera among the Balkan troops. The Liverpool school will set out the work that is being carried on against yellow fever and sleeping sickness, diseases in which the school has specialized for a long time. The admiralty will exhibit what has been done by the fleet surgeons in the matter of undulant fever, more commonly known as Malta fever, and due to

the goats of the island. The war office will take up that scourge of all armies, typhoid fever, and will depict the results of the study in the prevention and cure of the disease. Plague comes under the direction of the India office, and Dr. Andrew Balfour, of the Egyptian service, will make a special exhibit dealing with leprosy and other eastern diseases. Most, if not all, of the exhibits will make an important feature of the part played by flies, mosquitoes, fleas and rats in the distribution of disease. Part of the display is intended to inform the public how best to guard against these insect pests. Mosquito-proof houses, mosquito-proof clothing, and even mosquito-proof books are to be on view. A rat-proof house will be included in the departmental exhibits. There will be several examples of foods which have been deprived of their nutritive qualities, such as polished rice, which causes beriberi. The Liverpool school, which deals with this subject, will exhibit tinned foods from which the nutritive properties have been withdrawn in the process of preserving.

THE Arkansas general assembly has appropriated \$36,000 for the medical department of the University of Arkansas for the biennial period ending March 31, 1915.

LAKE ERIE COLLEGE has obtained the sum of \$200,000 for general endowment.

THE Tucker fund committee at Dartmouth College has established a fellowship of the value of \$1,200 which may be renewed for a period of three years; the holder of the fellowship may study at an American or foreign university and at its expiration must be prepared to accept an instructorship at Dartmouth College.

DR. CHARLES F. MYERS, of New York City, has bequeathed \$25,000 to Acadia University, Nova Scotia, to establish a professorship of biology.

MR. AUGUSTUS NASH has bequeathed the residue of his estate in trust to pay a near relative the income during life, and afterwards to pay the capital sum to Bristol University in the hope that it may be used to ad-

vance natural sciences, particularly chemistry. The sum will be about £18,000.

THE four largest courses in Harvard College last year were government 1 with 479 undergraduates, economics 1 with 438, philosophy E (elementary psychology) with 373, and chemistry 1 with 333. The other two courses which had over 200 undergraduates were philosophy A, Professor Palmer's course on the Greek philosophy, with 272, and history 1 with 250.

THE vice-chancellor of the University of Cambridge has appointed April 19 for the election to the Plumian professorship of astronomy and experimental philosophy, vacant by the death of Sir George Darwin. Candidates are requested to send their names to the vice-chancellor on or before April 11.

PROFESSOR HENKEL, of Königsberg, has been appointed director of the institute of pathology at Breslau, as successor to Professor Ponfick.

PROFESSOR HOFFMAN, of Prague, has been appointed to succeed Professor L. Hermann as director of the institute of physiology at Königsberg.

#### DISCUSSION AND CORRESPONDENCE

##### A SIMPLE FORMULA FOR COMPUTING GYROSCOPIC FORCES IN AN AEROPLANE

THE recent letter of Mr. James Means, in SCIENCE for December 13, 1912, has called renewed attention to the problem of the gyroscopic action of a revolving motor as affecting the safety of an aeroplane. The following simple formula for computing the magnitude of this gyroscopic action is offered as a contribution toward the symposium suggested by Mr. Means.

We shall regard the rotating motor as consisting essentially of a single wheel or disc, whose axle is supported by two bearings at known distances from the center of the wheel.

If the aeroplane is compelled by the rudder, or by a sudden gust of wind, to change its direction of flight, this compulsion may be thought of as due to the pressure of a flat board against the side of the axle, at a point,

say, in front of the wheel. As is well known, the axle will resist this pressure on account of the gyroscopic action of the rotating wheel, and will *strive to move off at right angles to the impressed force*, and in so doing, will *strive to carry the whole aeroplane with it*. If the wing surface of the aeroplane is large, this motion will be practically entirely prevented by the resistance of the air, and the result of the gyroscopic action will be the setting up of *internal stresses* in the framework of the machine.

The object of the following formula is to provide a simple means of computing the maximum value of these internal stresses in any given case.

Let  $a$  = the distance between the bearings, measured along the axle, in *feet*, and let  $P$  = the pressure, due to gyroscopic action, on each bearing, in *pounds*. Then  $P$  is given by the following formula:

$$Pa = (0.00034 \dots) W r^2 N n,$$

where

$W$  = weight of the rotating wheel, in *pounds*,  
 $N$  = angular velocity of the rotating motor, in *revolutions per minute*,

$n$  = the angular velocity with which the aeroplane is turning out of its path, measured in *revolutions per minute*, and

$r$  = the radius of gyration of the wheel about its axle, in *feet*.

*Note 1.*—A fair estimate of the radius of gyration can be obtained by a mere inspection of the linear dimensions of the wheel. For example, if the wheel were a homogeneous disc of radius  $R$ , then  $r = (0.7)R$ , approximately; while if all the material were concentrated in the rim, then  $r = R$ ; intermediate cases can be judged by the eye.

*Note 2.*—The coefficient 0.00034 ... represents the value of  $\pi^2/900g$ , where  $g = 32$  ft. per sec. per sec. If the lengths  $r$  and  $a$  are measured in *centimeters* instead of in *feet*, this coefficient must be replaced by 0.0000112 ... If  $r$  and  $a$  are measured in *inches*, the coefficient is 0.000029 ...

As an illustrative numerical case, suppose  $W = 167$  lbs. (which is the actual weight of a fifty-horse power Gnome motor),  $N = 1,200$

revolutions per minute,  $n=5$  revolutions per minute (estimated), and  $r=2/3$  ft. (estimated). Then if  $a=1$  foot, we shall have  $P$ —about 150 lbs.; or, if  $a=2$  ft.,  $P=75$  lbs., etc.

It thus appears that under ordinary conditions of flight, the effect of these gyroscopic forces could hardly be serious.

In conclusion, we note the following simple rule for determining the *direction* in which the force  $P$  will be exerted. (This rule was first published by the writer in the *Engineering News* for June 21, 1910. See also *The Scientific American* for November 23, 1912.)

Imagine the deflecting force (that is, the force which compels the aeroplane to change its direction of flight) to be due to the pressure of a flat board against the spinning axle (say in front of the motor), and *note the direction in which the axle, if rough, would tend to roll along the board*; this will give the direction in which the (forward) end of the axle will tend to move as the result of gyroscopic action—that is, the direction in which the force  $P$  will act against the (forward) bearing.

For example, suppose the axle is spinning in the clockwise direction, as seen by an observer looking forward, and let the aeroplane make a sharp turn to the *left*; then the forward end of the axle will strive to *rise*. Similarly, if the aeroplane makes a sharp dive *downward*, the forward end of the axle will strive to turn to the *left*.

#### FUR-BEARING MAMMALS: AN UNAPPRECIATED NATURAL RESOURCE

The manor of living nature is so ample, that all may be allowed to sport on it freely; the most jealous proprietor can not entertain any apprehension that the game will be exhausted, or even perceptibly thinned.

In such wise did Dr. Richard Harlam, writing in 1825, comment on the inexhaustibility of our natural game resources. As late as 1857 the following in substance appears in the report of an Ohio state senate committee:

The passenger pigeon needs no protection. Wonderfully prolific, having the vast forests of the north as its breeding grounds, traveling hundreds of miles in search of food, it is here to-day and elsewhere to-morrow, and no ordinary destruction can lessen its numbers, nor can those killed be missed from the myriads that are yearly produced!

The tragic story of the passenger pigeon is familiar to every one. Not so familiar, perhaps, are similar stories which may be told of other species. Fortunately, there is a growing realization that our national resources in wild life are rapidly dwindling, and attention is being directed toward checking the extermination.

This consideration comes not a moment too soon. Unless protective laws are enacted before a species is nearly extinct they can not ordinarily avail much. Nevertheless, vigorous efforts should be made continually not only to conserve species which are still plentiful, but to preserve species which, through our lack of foresight, are on the verge of extinction.

There is, however, one department of our fauna which, in the opinion of the writer, has hardly received its deserved quota of attention. I refer to the several species of fur-bearing mammals whose pelts have a commercial value. The species concerned include the bear, raccoon, skunk, badger, otter, sea otter, mink, marten, fisher, red fox and wolverine.

It is estimated on fair authority that there are within California alone trappers in the proportion of ten to the county, each of whom makes a possible average of five hundred dollars from his annual catch. There are fifty-seven counties, so that five hundred and seventy persons with a total income for the fur season of \$285,000 a year would on this estimate be resident in the state. Two hundred and eighty-five thousand dollars is the interest at four per cent. on \$7,125,000. This, or even a quarter of it, would seem to be enough of a commercial asset to be worth at least some legislative consideration.

On the basis of figures quoted by Ernest Thompson Seton<sup>1</sup> it appears that an extremely

<sup>1</sup> "Life Histories of Northern Animals," 1909.

conservative estimate would place the revenue to North America as a whole for the last seventy-five years from the furs of the raccoon, badger, wolverine, fisher, marten, mink, otter, red fox and large striped skunk at \$222,735,000, and to the United States at \$113,950,000. This is an average value per year of a little less than \$3,000,000 to North America as a whole, and \$1,500,000 to the United States. Three million dollars is the interest at four per cent, on \$75,000,000 and \$1,500,000 is the interest at four per cent. on \$37,500,000.

Thus a conservative estimate shows that \$37,500,000 is the "capital invested" by the United States in the fur-bearing mammals listed. These figures, while not especially large, do indicate that the fur value of these species has been appreciable! It should be remembered, too, that the furs of such damage-doing species as bear, coyote, wolf, mountain lion, lynx and wild cat are not listed in this estimate. That the fur trade total would be considerably swelled by the inclusion of the last-named mammals is indicated by the fact that Brass<sup>2</sup> has shown that the *annual* value of all North American furs during the years 1907-09 averaged one hundred million marks, or about \$25,000,000. My estimates given above are probably below the actual figures even for the species included. Twenty-five million dollars is the interest at four per cent. on \$625,000,000, which represents the approximate money-value of all North American fur-bearing mammals.

It is clearly apparent that there are good economic reasons for the protection of some of our mammals at least. The need of conservation is beginning to be keenly felt in California, where trappers in the Sacramento Valley recently testified to the writer that practically all fur-bearing species are rapidly decreasing. There is much wanton destruction of these animals during the summer season when their fur is worthless. The grizzly bear, the noblest member of our California fauna, is now practically extinct. The sea-otter, possessing the highest fur value of all our mammals, formerly existed in great numbers

off the coast of western America, and is also a vanishing species. The dismal story of dwindling numbers and final extinction seems about to be repeated in the cases of certain animals with which we are now dealing as though the "manor of living nature" was inexhaustible.

We are confronted with two facts: first, America's crop of fur is economically profitable, and second, the mammals on which this harvest depends are in most cases decreasing in numbers. We may dispose of these mammals in one of two ways: (a) They may be appropriated to man's use as rapidly as possible, with no thought of future supply. Their money-value thus becomes a perfectly definite sum, which can not be added to when the species become extinct. (b) They may be wisely conserved, heed being paid to the future. Their economic value under this method would either remain at about the figure at which it now stands, or would increase, and the fur-bearing mammals would be of permanent instead of transitory worth in dollars and cents. For instance, in California we could count on a quarter of a million dollars coming into the state annually which would not otherwise find its way here.

Upon proposing legislation it becomes immediately apparent that there are difficulties. Several of the animals mentioned are charged with various offences against the farmer. Others are to some extent predatory on game fishes and game birds. There is strong suspicion in the minds of some that their depredations are in many cases not so serious as certain of the indictments against them would indicate. But the lack of information does pointedly emphasize the need for more data as to their numbers and habits.

Nature-history museums may be relied upon for some of these desiderata, but at best there is no doubt that our knowledge is yet fragmentary and inconclusive. A state trapper's license, be it ever so small, would give data as to numbers of trappers and amount of trapping done which would be invaluable to legislators desiring to adopt a wise conservation policy. Perhaps more important

<sup>2</sup> "Aus dem Reiche der Pelze," 1911, p. 356.

even than this would be a thorough investigation by the various state and provincial game or conservation commissions of the habits of the species concerned, with special reference to food preferences and commercial values.
